The Bayon, intended to be Buddhist, was adapted to Śaiva usage before its completion, and ultimately contained the statues of Hindu and Buddhist deities, the Deva Rāja (a lingam representing the king's divinity), and statues of deified royal ancestors. Its most conspicuous feature consists of the towers with enormous masks (representing Lokeśvara) on each face; but equally interesting are the reliefs in which almost every aspect of contemporary life is depicted. The Baphuon, c. A.D. 1000, is a typical, terraced, pyramidal structure (*prāṅg*), with median stairways leading to a stone gallery above. Of the many other temples built in less accessible sites, the Prāh Vihear may be mentioned; it is magnificently situated on a spur of the Dangrek range, overlooking a rolling panorama of uninhabited jungle. Angkor Wāt is the later Siamese designation of the most famous and most beautiful of Cambodian shrines, of which the true name is unknown, though there is reason to think the dedication was to Viṣṇu. The date is the early 12th century.

The 14th century temple of Īśvarapura at Bantēi Srēi is proof that the capacities of the Khmers were not destroyed by the earlier Siamese invasions. But the country had certainly been devastated and Angkor Thom abandoned by the 15th century, and when later inscriptions appear, they belong to the Siamese period, and Hīnayāna Buddhism has replaced the mixed Mahāyāna Buddhism and Hinduism which formed the state religion of the Khmers in the classical period.

CAMPĀ

Eastern Indo-China, now Annam, once the seat of great Cam kingdoms, must have been Hinduised at an early date, for we find traces of Hindu kingdoms both in the north and south as early as the end of the second century A.D. All the early, and much of the later architecture was wooden. The remains are of two periods, one classic from the seventh century to about 1100, the other that of the decadence. The sacred city of Mi-son was founded about A.D. 400, but the great brick tower now surviving was built on the site of the original wooden shrine soon after 600. The plan is square, but the cella is twice as high as it is wide, and the effect of height is increased by the narrow decorated pilasters which emphasize the vertical lines; the pyramidal roof consists of three diminishing storeys, repeating the form of the cella on a smaller scale. The decorative motifs include makara niches, geese with extended wings, both old Indian motifs, and acroteria silhouetted against the sky; on the whole we are reminded of Indian Gupta towers, and the pre-Khmer towers of Cambodia. In addition to this main shrine there are six great halls for the accommodation of pilgrims; for Mi-son was a sacred city rather than a place of habitation. Later, about 800, a great temple and monastery, the only important Buddhist buildings in Campā, were erected at Dong-duong by Indravarman II.; but the place was soon ravaged by the Annamites, who were continually pressing downwards from the north and ultimately accomplished the ruin of Cam civilisation. Sanctuaries were built again near the new capital of Binh-dinh at the beginning of the 11th century; the colossal towers of Duong-long, and those known as the Towers of Gold, Silver and Copper, are striking monuments. But it was no longer possible to build up great temple cities in honour of the gods. The Annamites penetrated even as far as Nha-trang, and took possession of the temple of Po Nagar; only Po Klong Garai remains in Cam possession, and here worship is still conducted.

SUMATRA

Sumatra, Suvarṇabhūmi, the "Land of Gold," Yavadvīpa of early Indian literature, received Indian colonists probably before the Christian era; in the 5th century Māhāyāna Buddhism was officially adopted as a result of a royal mission from Kāśmīr. Ī Ching passed by Palembang about 690 and found here a great centre of Sanskrit Buddhist learning. Before this time the great Malay kingdom of Śrīvijaya held for many centuries by the Sailendra dynasty had been established with the capital at Palembang, controlling thence the Malay Peninsula and probably Siam as far as Prapathom; this was the greatest maritime power in south-eastern Asia (Madagascar had been colonised by Hinduised Malays early in the Christian era).

An inscription at Vien Śrāh in the northern part of the Malay Peninsula records the erection there of brick towers and stupas. That of Kota Kapur in Bangka speaks of a military expedition to Java, and in fact, from before the middle of the eighth century the whole of central Java was subject to the Śailendras. The buildings there erected, however, will be discussed under Java (*see below*); in Sumatra proper the architectural remains are little known and not well preserved. (*See SUMATRA.*)

JAVA

The old Hindu kingdom of Tārumā in western Java is known only by inscriptions of 4th and 5th century date. The earliest architectural remains are those of the Dieng Plateau, where in the seventh or early eighth century stone was for the first time employed in Java as a building material. The plateau was not an inhabited city, but a place of pilgrimage, a temple city comparable with Gīrnār and Mī-son. Out of many more, eight temples survive; they are known by the names of the heroes of the *Rāmāyana*, but these appellations have nothing to do with their original dedication to Śiva. The Indian character of the architecture is conspicuous, and in all probability Indian architects were at work here. The construction is generally cubic, with strongly emphasized vertical and horizontal lines; the temples are two-storeyed, the roof repeating the form of the cella. The plan is square, and the walls are divided by pilasters into niches or panels with sculpture; a grotesque makara face crowns the doorways. This description applies to the four temples of the Arjuna group; but Caṇḍi Bhīma is a pyramidal tower in the northern Indian *nāgara* style with successive horizontal stages repeating the fundamental forms, cornices with dormer-arches framing *Gandharva* heads, and *āmalakas* at the fourth and fifth stages; no doubt a single *āmalaka* crowned the now ruined summit. East and south of the Plateau and at Mt. Ungaran there are numerous other small temples of the same period and style, but rather more freely, and exquisitely decorated.

We come now to the great monuments of the Śailendra period (*see above*; *SUMATRA*) which are easily accessible to visitors from Djokjakarta. In Caṇḍi Kalasan, a lovely but ruined building dedicated to Tārā, we find the first Buddhist temple on Javanese soil; the date is A.D. 778. This is a building of the Dieng Arjuna type, but the lateral niches are developed into side chapels, the ornament is more elaborate, and there are delicate strips of floral tracery between the plain pilasters. Near by is the three-storeyed rectangular Caṇḍi Sari. Caṇḍi Mendut which is near Borobuḍur is similar in plan, but there are no side chapels; on the other hand there is an open sculptured vestibule, and the exterior walls of the cella are richly decorated with figure reliefs. (*See JAVA; see BATIK.*)

Borobuḍur.—Borobuḍur ("Many Buddhas") is wonderfully situated on an eminence commanding an extensive view of rice-fields and more distant towering volcanoes; it is a hill that has been terraced and clothed with stone. It is in fact a low pyramid composed of successively receding platforms with re-entrant angles. The structure is thus exactly analogous with that of contemporary buildings in Kāśmīr, and that of earlier stupas in the Panjāb and Afghanistan, and the Rawak stupa in Turkistan, which are similarly provided with extensive basements having median stairways on one or four sides, though none of the Indian examples has more than two terraces, so that Borobuḍur represents a more developed type. (For the sculptures *see* *INDONESIAN AND FARTHER INDIAN ART.*) Borobuḍur cannot be exactly dated, but was probably built at the close of the 8th century.

Caṇḍi Sewu Prambanam is a Buddhist temple which dates from the early 9th century. The large central shrine represents a further development of the Caṇḍi Kalasan design, with side chapels open to the exterior, and niches containing images. Around it, within the large area enclosed by the *prākāra* are two double series of small independent chapels, about 250 in number. The order and formality of the design are conspicuous.

After the "Restoration," c. A.D. 860, the Hindu kings of Central Java erected other great buildings at Prambanam. The Caṇḍi Loro Jongrang group consists of three large terraced temples dedi-

cated to Brahmā, Śiva, and Viṣṇu, and some smaller shrines, within the same enclosure. The Śiva temple is typical; the actual shrine occupies the summit of a steep truncated terraced pyramid with median stairways on three sides leading directly to the main shrine and side chapels above. The whole site may have been a royal mausoleum as well as a place of ordinary worship. Nearby is the Buddhist Caṇḍi Plaosan.

These temples were no sooner built than abandoned, for about A.D. 915 Central Java was deserted, and the further development of Javanese architecture must be studied in the East and in Bali.

At Caṇḍi Lalatunda and at Belahan there are sculptured bathing places built by Udāyana and by his great son, Erlanga. The best known monuments, however, belong to the 13th and 14th centuries, the time of the great capitals at Singasāri and Majapahit. At Singasāri, Caṇḍi Kidal is a Śaiva, and Caṇḍi Jago a Buddhist temple, but there is a mixture of the two cults amounting almost to fusion, as was also the case in Cambodia; a like condition survives in Bali at the present day. In far eastern Java the great Buddhist shrine of Caṇḍi Jabung dates from 1354; the circular tower, unique in Java, stands on the usual high rectangular terraced basement, the transition from base to tower being skillfully effected. At Panataran near Blitar there is a large Śaiva temple complex, recently excavated and partly restored; the basement of the main temple is square and terraced, with the usual recessed corners. The associated gates and the sculpture are already in a style forecasting that of Bali.

Bali.—Bali, where alone in Indonesia Hinduism and Buddhism survive as practised cults, most probably had early and direct relations with India; but we have also to reckon with the migration of Javanese exiles to Bali at the close of the 15th century, by which time practically the whole of Java had received Islam. In Bali the only important early remains are the royal tombs at Tampaksiring, dating from the 11th or 12th century, and the Pura ye Ganga temple, more or less in Panataran style, dating from the 14th or 15th century. The more modern temples of Sangsit, Bangli, Batur, Kesiman, Den Pasar, etc., consist of groups of small independent shrines enclosed by walls having high roofed gateways; with rich sculpture in limestone, in fantastic forms and high relief.

INDIAN DESERT, THE. Between the ancient Aravalli mountains and the wall-like front of the recently folded arcs which carry the Indo-Baluchistan frontier, and from the shores of the Arabian sea to within an average distance of c. 80 m. from the Himalayas, extends a lowland exceeding 200,000 sq.m., with an annual rainfall of less than 15 in. and a population of about 15 million. At one extremity it touches the northern tropic; at the other it passes beyond 32° N. lat. It includes most of that part of the Punjab which constitutes "The Land of the Five Rivers," together with the adjoining trans-Indus districts of Dera Ghazi Khan and Dera Ismail Khan; the whole of Sind and, to the immediate north, Kachhi (Kalat). The western hem of south-east Punjab must be added also. Native States territory constitutes a solid block extending from the Sutlej-Indus line, east of Sind, to the Aravallis, including Bahawalpur (*q.v.*), and to the south the Rajputana States of Bikaner, Jaisalmer, and Jodhpur (*qq.v.*). Native territory touches the Indus again for a short distance below Sukkur where Khairpur State, hinging on to the west of Jaisalmer, breaks across Sind to the river. Finally Cutch State passes down from Jodhpur to the seaboard south of Sind.

A range of 10° of lat. implies considerable climatic diversity, and the area embraced leaves room for topographical variety. Yet it remains a major natural entity, the character of which is conveyed in the title "Arid Lowland." The tract has a general slope from the Himalayas to the Arabian sea, *i.e.*, north-east to south-west. Along its inner margin, in Punjab, the land between the rivers (*doabs*) rises to c. 700 ft.; but the western portions of the *doabs* and south of the Sutlej, almost all Bahawalpur, lie below the 500 ft. contour line. The 250 ft. contour line cuts the Indus river as it enters Sind, the heart of which province is well below this; the rest, with the conspicuous exception of the Kohistan, not much above it. To the south-east towards the Aravallis, the lowland attains a general level of over 1,000 ft. whence it grades down north-westwards, *i.e.*, traversing the prevailing slope at right angles. Except for a fringe of Jaisalmer, and the basin of the Luni river draining south-east to the Runn of Cutch, all Rajputana stands well above 500 ft. and betrays its physical "betweenness." Its deep mantle of aeolian deposits allies Rajputana superficially with the alluvial expanse upon which it encroaches. But it is not so completely destitute of solid rocks, and these, rising as low heights above the sandy surface, indicate a deep-seated unity with peninsular India as a coastal margin shelving from the Aravallis towards the seas, persisting to the north until late geological time.

Climate.—Climatically the tract is one of extreme temperature range, daily and seasonal. This is tempered somewhat along the coast but increasingly marked northwards. November to February is warm, with a mean daily temperature of 55°–70° F. The minimum falls in January. The designation "Cold Season," which is applied to this period (particularly the latter half), serves to emphasize the contrast with conditions prevailing during the rest of the year; namely, the low night temperatures with liability to frequent frost in the Punjab (Khushab mean min. Jan. 41.5° F, lowest recorded 25.0° F) and north Sind, though elsewhere such occurrences are very rare; the limitation imposed upon agriculture by the exclusion of essentially tropical plants at this season; and, lastly, the relief, which its duration affords to Europeans. Pressure is high in relation to the neighbouring seas, and only light winds blow from north-west and west. Except during the passage of shallow cyclones from across the North-West Frontier, toward the south-east, bringing a little rain to the Punjab fringe (rarely elsewhere), cloud is absent. March to October is hot. From May to July the mean daily temperature exceeds 90° F, with the maximum in June. Afternoon readings of 110° to 120° F

are registered (Jacobabad 127° June 1919; highest ever recorded in India). The rising temperature initiates a reversal in pressure and amid the changing conditions duststorms are generated.

Winds from the west and south-west are well established by April and persist until October, blowing with increasing strength as the depression deepens over the land until they reach their final expression in the south-west monsoon proper. But the air currents now entering the lowland on this side emanate from the dry land belt about the head of the Arabian sea. Hence they are not saturated like those, which, originating over a broad ocean, impinge on the Bombay coast; but only "stray" just north of the Aravallis. They confer even scant benefit to the immediate coast fringe; beyond, they desiccate. Since also the Bay of Bengal branch of the advancing monsoon, which enters the lowland from the east on a downhill journey to its barometric goal, has already served the whole Gangetic plain, its remaining moisture is soon exhausted. Thus of the 213,110 sq.m. actually under review 47,590 receives less than 5 in. per annum; 95,560 5 to 10 in., 69,960 10 to 15 inches. The following illustrates briefly the salient features of distribution, and how precipitation shrinks north, south and east towards Upper Sind and Kachhi:

Stn.	June-Sept.	Var.	Oct.-Feb.	Var.	Mar.-May	Total (in.)
Shahpur .	9.6	33	2.5	44	2.2	14.3
Sirsa .	11.4	37	1.6	7.2	1.3	14.3
Pachbhadra .	11.3	33	.7	8.1	.8	12.8
Bikaner .	9.2	67	1.0	7.5	1.1	11.3
Jaisalmer .	5.9	53	.5	8.0	.4	6.8
Multan .	4.9	51	1.1	5.8	1.1	7.1
Karachi .	6.1	80	1.3	7.1	.3	7.7
Jacobabad	2.7	75	.9	7.1	.5	4.1

Var. (variability) indicates departure from average seasonal rainfall as registered in half the years during 1890–1923, expressed in percentage. It is one way of illustrating the violently fluctuating régime. In general, March to May returns are insignificant.

Water.—It is a truism that natural boundaries are zonal not linear; and generalizations concerning the biological effectiveness of rainfall are dangerous. Space forbids qualifications, yet it may be accepted that over the lowland precipitation is such that it precludes the transformation of the surface by permanent cultivation, and that over those parts which lie beyond the sphere of running water a desert landscape prevails. At once, therefore, it claims a continuous area of just over 100,000 sq.m. cut off from effective water circulation. This involves Bikaner, with Jaisalmer and nearly all Jodhpur; Bahawalpur practically to the north-west railway which runs parallel to the Sutlej; the Runn of Cutch, and north of it as much of Thar and Parkar district (Sind), Khairpur State, and Sukkar district (Sind) as lie east of the Nara river (properly canal). Its name "Thar" refers to the sandhills accumulated by the prevailing winds which transport thither the saline dust picked up over the Indus delta and the Runn. Two types of sandhills are recognized. (i) Longitudinal (Sindhi *Bhitis*), parallel ridges aligned north-east south-west, *i.e.*, parallel to the prevailing winds. The *bhitis* are restricted to the west, *i.e.*, Thar and Parkar south of Umars, eastwards to the Luni basin. They reflect greater wind force than (ii) Transverse type, to which they give way, through intermediate forms, north-east of Umars. These lie at right angles to the wind but are less regularly aligned than (i). The marginal dunes rise to about 200 ft. above the general sandy surface and are relatively permanent. Further inland they are lower, in constant motion, and the landscape tends towards a low plateau of deep, loose sand, reminiscent of a billowy sea.

Deserted by a "westerling" parent, the feeble monsoon streams which struggle across south-east Punjab, between the Sutlej and Jamna rivers, succumb before the sand ere the Rajputana border is reached. The Luni river is the only significant watercourse within the area. It receives several Aravalli streams from the south-east and is at least a support to the subsoil water within its bend; but it loses itself in sand at the head of the Runn.

Salt.—The salinity of the soil, characteristic of the whole low-

land and here very marked, is sufficiently accounted for throughout Thar by the action of the wind, bringing material from the seaboard. The evaporation of subsoil brine is common over Rajputana (particularly Pachbhadra neighbourhood) and also beyond south-west of Delhi, in Multan and Muzaffargarh. The Rajputana salt lakes, representing the fixation of salt washed into basins of internal drainage, are marginal to the desert. Of these, Sambhar, on the Jodhpur-Jaipur boundary is the largest. It lies in a closed depression in the Aravalli schists (1,184 ft.). Its maximum spread is 90 sq.m. and during a normal monsoon it averages 4 ft. deep in the middle, but is dry the greater part of the year. The upper 12 ft. alone of saliferous silt forming its bed represents a salt reserve of about 54,000,000 tons. The lake is worked on lease by the Government of India, and the salt extracted is railed to Sambhar at the eastern end of the lake, whence it is distributed (average annual yield 1918-19 to 1922-23, 230,340 tons). Lesser lakes, of scant importance, occur to the north-west.

Gypsum, also occurring on the margins of some of the lakes, may prove more important in the future. In Sind and Khairpur, where the floor of alluvial clay remains uncovered or only thinly mantled with sand, shallow though often large expanses of water known as *dhands* are common in the hollows (*talis*) between the sandhills. They are fed by rain water percolating through the sand and emerging as a spring (*sim*) above the clay. Prior to the controlling of the Nara river many *dhands* were replenished by its flood spills, but these have now mostly dried up. *Sim* water is often sweet, and gives rise to fresh pools close to where it emerges and lying a few feet above the *dhand* proper, which is either alkaline or saline, rarely fresh, its particular nature being recognizable from its fringe of vegetation. All *dhands* shrink seriously after rain; the smaller ones dry up. The mineral *trona*, from the alkaline *dhands*, supports the soda (*chaniho*) industry of Khaipur State and Nawabshah district (Sind). Saline *dhands* yield salt and gypsum.

Flora.—A varied, open, shrubby and coarse herbaceous vegetation is characteristically present, salt lovers being conspicuous. On sweet, damp bottoms, and after rain, good grass abounds. Thus fodder exists for large numbers of cattle, sheep, goats and camels; villages are scattered everywhere.

When rain is propitious, millets (principally bajra) are raised and husbanded to eke out a milk diet supplemented otherwise only by such imported grain as the profits of the pastoral industry and associated crafts, such as the making of blankets, felts, *lohis* (coarse shawls), ropes, bags, brushes and leather goods render possible. Typical desert *talukas* of Sind show a population density per square mile of less than 20 (*cf.* Diplo. 12; Chachro 18); Jaisalmer the "core" of the desert has an over-all density of 4 per sq.m.; Bikaner gives 28 (Bikaner city 69,410); Jodhpur 53 (Jodhpur city 73,480), but a heavy allowance must be made for that part of the State outside the essential desert. Roughly, Thar carried c. 2½ millions, largely marginal.

The Runn of Cutch (Rann of Kachh), embracing c. 8,000 sq. m., while an integral part of the desert, possesses a distinctive character. It is a low-lying salt-impregnated alluvial tract. Seemingly uniformly level, it has a general imperceptible slope seaward, while minor irregularities give shallow surface depressions. When the surface is dry it is hard and polished, "even a horse's hoof hardly dents it in passing." During the south-west monsoon, however, it is flooded by the waters of the Luni, Puran, Banas and other rivers assisted by rain remaining on the hard surface, but the view that at this season the sea invades it (the sea level is raised 4 to 5 ft.) has been disproved and abandoned. During flood the water varies in places from a few inches to some feet, but after it subsides evaporation proceeds until only salt remains.

Lying in a belt liable to pronounced seismic disturbance, the Runn suffered severe displacement in 1819; depression increased the "rann" proper, but aeolian deposits have diminished it since. It is a range for wild asses. The impoverishment of the Runn and much of what is now Thar reflects the "westerling" of the Indus and associated Punjab rivers. A map shows that the streams making for Rajputana across the low Sutlej-Jumna watershed converge towards a large dry water course (the Ghaggar), which runs

parallel to the Sutlej and is traceable beyond through Sind to the Runn, roughly via the east Nara and Puran. This is the Hakra, or "Lost River," fed formerly by the Sutlej (possibly at one time by other Punjab rivers), and in its lower course (as the Mihran of Sind), by the Indus. Such was the known condition in the 8th century A.D. Subsequent probably to phenomenal flooding in north Punjab, placed in the 14th century, a rearrangement of drainage initiated the decline of the Hakra. First a "westerling" Indus ceased to feed its lower reach; eventually the Sutlej completely deserted it and passed to the Indus via the Beas. By 1790 the Hakra was dead. The tapping by bunds of the waters latterly feeding the Puran from an Indus distributary assisted to complete the dereliction of the abandoned delta (the Runn).

Irrigation.—Outside Thar, the immediate valleys of the rivers sustained by the snows of Himalayas, tree-lined and recuperated by inundations, break the arid continuity, while as a result of irrigation achievement the desert survives only in fragments. Consequent upon the melting snows, the Indus and rivers of Punjab begin to rise in March, and normally spill over the land in mid-June. Floods culminate in August, and the rivers fall fairly rapidly to a minimum about February. From antiquity channels have been dug to utilize the rising waters. Such inundation canals are necessarily restricted to the lower marginal lands, *i.e.*, mainly newer alluvium (*Khadar*), which in Punjab lies 10 to 50 ft. below the older alluvium (*Bhangar*) comprising the *doabs*, and varies from 4 to 10 m. wide. Hence they occur mainly where the "Five Rivers" converge to form the single artery continued in the line of the Indus, and attain their maximum development in Sind, where the widening *Khadar* merges into truly deltaic land. Many of these canals existed prior to British rule; they have been improved and others added. Since inundation canals function only during the floods and fluctuate with the natural level of the water in the river their shortcomings are obvious. Yet they play a big part. At present they are virtually the only form of irrigation in Sind, and they serve c. 1½ million acres in the Punjab. Thus (average annual area irrigated 1923-24 to 1925-26, in acres): Upper Sutlej canals, 320,237; Lower Sutlej canals, 342,972; Indus Inundation, 234,945; Muzaffargarh Inundation, 333,694; Chenab Inundation, 185,440. In addition, the Sutlej serves c. 900,000 ac. in Bahawalpur and there is a small canal in Dera Ismail Khan.

Agriculture.—It is, however, to the expansion of great perennial systems over the broad backs of the Punjab *doabs*, and the development of model agricultural colonies thereon, that the elimination of the desert between the Jhelum-Chenab on the one hand and the Sutlej on the other is due. Details of what this has meant must be omitted, but the following Punjab census (1921) return is noteworthy: "In 1891 the population density contour line, 100 per sq.m., which enclosed the oasis of Multan was no less than 160 m. distant from the general 100 per sq.m. density line. Since 1891, however, due to the development of the Lower Jhelum, Lower Chenab and Lower Bari *doab* canals the line has advanced at an average rate of c. 10 m. per annum, and in 1911 Multan had been turned, from the point of view of population, from an island into a narrow-necked peninsula." Agriculturally it has meant the establishment of c. 1 million acres of acclimatized American upland cotton with a staple of c. 1 in., and a great wheat expansion.

The following gives the area now being served; canals marked* lie entirely in the arid zone, the others affect its margins (average annual acreage 1923-24 to 1925-26): Lower Chenab*, 2,478,210; Lower Jhelum*, 868,064; Upper Jhelum, 326,786; Upper Bari *doab* 1,254,234; Lower Bari *doab** 1,165,109. The Sutlej valley project, now in hand, will convert certain inundation canals dependent on that river into perennial, and assure the flood supply of the rest, while extending irrigation into the Bahawalpur and Bikaner fringes of Thar. When complete it will irrigate 5,108,000 ac., including 2,075,000 perennial and 2,033,000 non-perennial; 3¼ million acres at present waste, will be available for colonization. Representation by the Bombay Government has led the Government of India to hold up further undertakings by Punjab pending investigations into Indus river supplies; the position is difficult and a Central Indus Board is mooted.

Projects.—Punjab is anxious to carry out two big tasks at

least. Firstly, to reclaim the Sind-Sagar *doab* by the Thal project, which would carry water from the Indus at Kalabagh over Mianwali and Muzaffargarh above its inundated "tail." Secondly, to construct the Bhakra dam on the Sutlej where it emerges from the hills, with a canal to supplement the Sirhind and west Jumna canals (feeding 728,953 and 1,591,629 ac. respectively), and to extend irrigation in Hissar and Bikaner. This would give sorely needed protection to the arid skirt of south-east Punjab, at present served only by the lower reaches of the canals mentioned (assisted by the small Ghaggar inundation canals), and also nibble a little off east Thar.

The recession of the western mountain wall enables the Indus, after receiving the united volume of the Punjab rivers, to enter Sind as a south-west flowing river. Near Schwan it turns south in the presence of the Laki range but manifests its "westerling" tendency again in its final struggle seaward. The bifurcation of the Ochito and Haidari is quoted as the head of the delta; but, of course, throughout Sind the river is really deltaic, flowing on a ridge above the land on either side, restrained in parts by embankments, but requiring more to curb its devastating moods, while the lower part of the province is riddled with its dead channels. Only in the gorge between Sukkur and Rohri, where it traverses a gap at the north extremity of low hills running for 40 m. south from its left bank, and in the Kotri neighbourhood is its channel constant. Its sphere of influence, between the mountains on the west and Thar on the east, defines settled Sind. The cultivable area commanded by canals dependent on it approaches nine million acres of which, in 1924-25, 2,168,682 ac. were irrigated under the right bank systems and 1,557,201 under the left. As the Indus is not yet weir-controlled, technically all its irrigation is by inundation, its canals functioning only during the flood season (June to early October). One or two, however, receive a little water in the "cold" season, and the Jamrao canal, weir-controlled and fed from the east Nara supply channel (linked with the Indus but not weir-controlled itself), is truly perennial. In order to afford an assured supply at all times, the Sukkur Barrage project, after long years of discussion, has recently been undertaken. The barrage is to be placed 3 m. below the Sukkur gorge. Briefly, four canals will take off the left bank and three (one a purely rice canal) off the right bank. They will take up the area south of Sukkur at present under inundation irrigation, and in addition will enable a considerable area of waste to be cultivated. Actually 6½ million acres of cultivable land will be commanded, and it is hoped to feed 5½ million acres annually, of which two million represents existing inundation irrigation to be given an assured supply. Of improved cotton alone 700,000 ac. per annum are anticipated. The project will take c. 40 years to complete, but big developments are expected in ten years' time.

Westwards beyond the sphere of the Indus, the desert landscape is at once established, and the irrigated patches of *daman* (clayey soil) created and sustained by flood torrents searing the mountain wall, only throw the naked hideousness of the limestone rampart into bolder relief.

INDIAN HEMP (*Apocynum cannabinum*), a North American plant of the dog-bane family (Apocynaceae), native to fields and thickets from Quebec to British Columbia and southward to Florida and Lower California. It is an erect, often much branched perennial, 1 to 4 ft. high, with smooth, oblong, opposite leaves, and small, clustered, greenish-white flowers, from each of which develops two very narrow fruit-pods (follicles), about 4 in. long,

containing numerous downy-tufted seeds. The tough bast fibres of the inner bark were utilized by the Indians for cordage. (See APOCYNACEAE; DOG-BANE.)

INDIAN INK or **INDIA INK**: see INK.

INDIAN LAW. The law in force in British India may conveniently be divided into six heads: (1) The law expressly made for India by the British parliament, or by the sovereign. (2) English law in force in India though not expressly made for India. (3) The law made by persons or bodies having legislative authority in India. (4) Hindu law. (5) Burmese Buddhist law. (6) Mohammedan law. The first three of these are frequently described as Anglo-Indian law. They are with rare exceptions territorial, *i.e.*, they apply generally, either to the whole of India, or to a given area, and to all persons within those limits. The last three are personal, *i.e.*, they apply only to persons who answer a given description.

Law Expressly Made for India by the British Parliament or Sovereign.—There are in existence many Acts of parliament relating to India. Many Acts were concerned with constitutional law, the powers of the East India Company, of the Board of Control, and of the governor-general, and, after 1858, with those of the Crown, the secretary of State and his council, the governor-general in council, and the other Governments of presidencies or provinces. These have now been consolidated in the Government of India Act 1915 as largely amended in 1919. This Act deals also with the high courts. Such courts have been established by charter at Calcutta, Madras, Bombay, Allahabad, Patna, Lahore and Rangoon, and some of the clauses of their charters are legislative in effect.

English Law in Force in India Though Not Made Expressly for India.—Before the wars with France in the middle of the 18th century the East India Company's possessions had been little more than trading posts, and the mayors' courts established by charter at the larger ones, such as Calcutta, were not generally concerned with anything but matters inside the settlements, and endeavoured to adjust these on the basis of English Law where British subjects were concerned. But, as shown in the historical section of INDIA (*q.v.*), by 1760 the company had become responsible for more or less of the administration of considerable territories in Bengal and southern India. Under Acts of parliament commencing with the Regulating Act of 1773 supreme courts were established, originally at Calcutta, and then, superseding recorders' courts, at Madras and Bombay. And it was held that they were to administer English law within those presidency towns, unless by their charters directed to administer some other law. The charters did direct them to apply to Hindus and Mohammedans their own laws in regard both to all matters of inheritance, succession and family law, and to matters relating to religion and caste. It was soon found that the law of succession and inheritance could not be administered without also administering that of marriage. Outside the presidency towns, when the company did finally take up the administration of justice, it did not at first purport to alter the law. It administered Hindu law to Hindus and Mohammedan law to Mohammedans, and retained, at least in Bengal and Madras, Mohammedan criminal law as the criminal law. Gaps in the law, and adaptations to new needs, had to be filled in by recourse to the principles of "justice, equity and good conscience" which Sir Henry Maine (*Village Communities*, 1881, p. 299) surmises to have often been, in the case of the subordinate courts, "applying some half-remembered legal rule learned in boyhood." And thus a good deal of English equity, and some English common law, came into the practice of the company's courts. And when the supreme courts at last recognized Hindu wills, they had to apply the methods of the English court of probate.

Legislative Law.—As a general proposition it would be true to say that wherever a British authority has legislated in India it has been largely influenced by the English law, and until 1909 British influences were predominant in the legislative councils. The present legislative authorities in India are:

(1) the central legislature, *i.e.*, the council of state and the legislative assembly, (2) the legislative council of each "governor's

province," and (3) (only in emergency) the governor-general. Their Acts deal with topics of every sort suitable for legislation. No legislative enactments of any kind passed in India before 1793 are now in force. In Bengal in the year 1793, 48 regulations, as they were then called, were passed in a single day, and it was assumed that all previous legislation in Bengal was thereby superseded. Similar regulations were passed about the same time, and the same assumption was made, in Madras and Bombay. As new territories were acquired by the Government of India, the existing regulations were in some cases extended to them, but in other cases this was not thought to be convenient, and for these territories the governor-general in council issued general orders, not in the regular way of legislation, but in the exercise of his executive power. Hence the distinction between "regulation" and "non-regulation" provinces. Any doubt as to the validity of the orders so made was removed by the Indian Councils Act 1861. The term "regulation" was dropped after the passing of the 3 and 4 Will. IV. c. 85 (1833), and since that time the word "Acts" has been in use. Acts are referred to by their serial numbers in the year of the sovereign's reign in which they were enacted by parliament.

At times since 1833 commissions have been appointed to draft laws prior to their introduction into the governor-general's legislative council, but this practice ceased before 1870. To the earliest of these commissions we owe the Indian penal code, much of the original draft of which was made by Macaulay. It was finally passed in 1860 and came into force in 1862. It leaves procedure to be dealt with in a separate code. It is based upon English criminal law, but in many points simplifies it and renders it easier to administer, while somewhat altering it in others. What is commonly called larceny in England and the United States is broken up into theft, criminal misappropriation and criminal breach of trust, for instance; and all offences are defined in language which is capable of plain interpretation. The best testimonial to the penal code is that, though it has needed some additions, it has stood without substantial alteration for about 65 years. Other parts of the law which have been codified are criminal procedure, civil procedure, contracts, wills of Hindus in the presidency towns and the old province of Bengal, wills and intestacy of Christians and of Parsees, probate and administration of all wills and of intestate estates, specific relief, registration of title, transfer of property, trusts and evidence. Sir J. F. Stephen was the draftsman of the Indian Evidence Act, which was passed in 1872.

The law relating to land revenue has been the subject of innumerable regulations and Acts of the Indian legislatures. A description of the revenue systems prevailing in India will be found in the article INDIA. The law which governs the relation of cultivators to those, whom for want of a better term we must call landlords, has grown to a considerable extent out of the revenue system. The view which was at first taken of this relation was unfortunately affected by English notions of the relation of landlord and tenant, but this view has been considerably modified in favour of the tenant by later legislation. Tenancy rights vary from province to province, and each province has its tenancy law, or perhaps two or more such laws applicable in different parts of the province. The scope of this article does not admit of an examination of them. The tendency is to encourage hereditary occupancy tenure at rents to be fixed periodically by the courts, or at least life-tenure. In Madras and Bombay much land is owned by the actual cultivators. And in northern India most small landholders cultivate some of their lands while tenants hold the rest of it.

The legislative acts of the governor-general in council from 1834 to date have been published by the legislative department of the Government of India. They are revised from time to time, and an annual volume published of each year's acts. The Madras code, the Bombay code, the Bengal code, the United Provinces code, the Punjab code, the Burma code, the Central Provinces code, the Bihar and Orissa code, the Assam code, and the codes of the small provinces have been published by the legislative department and revised editions are published from time to time. See also Baden Powell, *Land Systems of British India* (1892).

HINDU LAW

The Acts establishing courts of civil justice in the various provinces enjoin that Hindu law, or Mohammedan law, or (in Burma) Buddhist law is to be applied to the adherents of those faiths in such matters as succession, inheritance, marriage, divorce, dower, guardianship, minority, family relations, caste or any religious usage or institution. The actual lists vary in the different Acts. Indeed in Bombay the words used are "the usage of the country in which the suit arose; if none such appears, the law of the defendant." In Bombay, the Punjab and Oudh, custom, if proved, overrides law, and in Madras, the Central Provinces and Burma it is given the same force as law. Of course a saving is made of anything actually repealed by a statute or Act, and of all things contrary to public policy. For many purposes Jains and Sikhs are Hindus.

The section on legal literature in the article SANSKRIT (*q.v.*), mentions the written sources of Hindu law. The more ancient of these are regarded as sacred, and, as it is sacred, Hindu law is theoretically unalterable. But in fact it has changed, by admitting peoples wholesale into Hinduism who brought their customs with them, by slow local and family changes, and by adaptations to historical, political, economic and social changes. As to custom, indeed, Manu's code says "immemorial custom is transcendent law." In actual practice, and apart from modifications by custom, Hindu law as administered in the courts is substantially derived from the commentaries of the great commentators. For most purposes the chief among these are the *Daya Bhaga* of Jimuta Vahana in Bengal proper only, the *Mitakshara* of Vijaneswara all over India, and the *Vayavahara Mayukha* of Nilakanta in western India. The *Daya Bhaga* in Bengal, and the *Mayukha* in Bombay overrule the *Mitakshara* where they differ from it, and in the case of the *Daya Bhaga* the differences are so far-reaching in the matter of family property and in the theory of inheritance that it is rightly held that there are two main schools of Hindu law, the *Mitakshara* school and the *Daya Bhaga* school. The former is divided into the Benares school (Upper India generally), which prefers the *Mitakshara* to all other commentaries at all points, the *Mithila* school (northern part of the province of Behar and Orissa), the *Maharashtra* school (western India) and the *Dravida* school (southern India). The effects of decisions of the judicial committee of the privy council and of the various high courts on Hindu law are similar to those of the English courts on English common law and statute law.

The Joint Family.—The striking feature of Hindu society and Hindu law is the joint family. It is the form, no doubt, in which the Aryan patriarchal family has survived in India. The joint family is seen at its weakest in Bengal, the region where Brahmanical ecclesiasticism has had its greatest effect, for the *Daya Bhaga* is based upon it. Brahmanical influence on law probably increased at the post-Buddhist Hindu revival, but seems to have had little or no effect in the Punjab, or among the Aryan, or Aryanized, peoples of the Himalayas. Among some of the Himalayan clans, who undoubtedly have Aryan blood in them, the joint family is more like the Roman family than it is among Hindus of the *Mitakshara* school in India generally. The joint family is so much taken for granted in the *Shastras* and the commentaries that it is scarcely described in them.

As the question of whether a family's land could be validly alienated probably did not arise until comparatively recent times, the distinction between the right to manage, on the one hand, and ownership with the right to alienate on the other, probably did not become an important point of law for many centuries. When it did arise, two conflicting theories emerged. One is that of the *Mitakshara*, that down to the great-grandson of a living ancestor a male Hindu acquires by birth a right of ownership as a coparcener in the ancestral family property. The other is that of the *Daya Bhaga*, that the living ancestor is the sole owner, with unfettered control and power to alienate, even for personal purposes, and that on his death his descendants in the direct male line who have no ascendant living inherit the property in distinct and specified shares, and may either divide it up or retain it as a jointly worked and managed property. Under the *Mitakshara*

no co-parcener's share is a definite thing, even if he has no ascendant living, until a partition is called for. Until that event occurs each co-parcener's share can, in a manner, be said not to be ascertainable. And when a co-parcener, even the common ancestor, dies his rights pass by survivorship, and not by inheritance. Under the *Daya Bhaga*, then, when the common ancestor dies the ownership passes in immediately ascertained shares to his heirs under *Daya Bhaga* law. But in such a case under the *Mitakshara* the ownership, that of the family, is unaltered, but in the family there is one co-parcener the less, and the distribution on a partition made after his death will differ from that on one made before it. And, while the property remains joint, there is no passing of it by inheritance. The nature of the ownership of joint property is not discussed in either the *Mitakshara* or the *Daya Bhaga*.

If a family of brothers governed by the *Daya Bhaga* keep their property undivided, then, upon the death of one of them, his share goes to his heir or heirs, who, in default of agnate descendants, may be his widow, his daughters, or the sons of his daughters, and in this last case his share will pass into another family, but it need not therefore be separated off by a partition. In a like case under the *Mitakshara*, if the deceased brother had any agnate male descendants they were already co-parceners in the family property, while his wife, his daughters, and the sons of his daughters could not be co-parceners. Upon his death there was one co-parcener the less in the family, and the distribution on a partition would be somewhat altered. As long as two or more co-parceners remain in a *Mitakshara* joint family, such property as it may own cannot pass out of it by inheritance.

There is a standing presumption that Hindus nearly related to one another by agnation form a joint family. When they are so far apart in blood as second cousins that presumption is not very strong. And there is some presumption that anything in the possession of a member of a joint family belongs to the family. However, Hindu law now recognizes self-acquired property, though it took a long time to do so, even as the *peculium* of Roman law was of slow growth. Gains of valour, science and learning made without help from family resources are the chief source of self-acquired property, apart from what is styled "obstructed inheritance." But when self-acquired property passes by inheritance to agnate descendants it at once becomes ancestral, and under the *Mitakshara* the inheritors, unless they have already separated from one another, hold it as an ordinary joint family co-parcenary. Under the *Daya Bhaga* the fact that each co-parcener has a known and particular share of which he can dispose in his lifetime as he pleases by sale or gift or in any other way, without being answerable to anyone, greatly simplifies questions arising out of alienations. But under the *Mitakshara* the dealings by a co-parcener with the share which would fall to him on a partition, and the rights of his personal creditors against that share, both while he is alive and after his death, have given rise to legal difficulties.

Non-inheritors.—A joint family will usually have among its members who are not co-parceners. Under the *Daya Bhaga* the wives of co-parceners, the male agnate descendants of co-parceners, and the unmarried female descendants of co-parceners or of their agnate descendants come into this category, as well as those who might in time be co-parceners but that Hindu law debar them from inheriting, e.g., those born deaf, dumb, blind or insane. Under the *Mitakshara* the dependent members will not include qualified sons, grandsons or great-grandsons of the senior generation of living co-parceners, for these are co-parceners themselves by right of birth, unless disqualified by any defects which debar from inheritance. But among the dependents there will be widows of deceased co-parceners. Under the *Daya Bhaga* such a widow without sons or agnate descendants will herself be owner, at least for her life, of her deceased husband's share. Under both schools these dependents must be maintained, out of the shares of their respective branches of the family in the case of the *Daya Bhaga*, and out of the general family fund under the *Mitakshara*. And, in theory, under the *Daya Bhaga* each actual co-parcener, which here means the owner by inheritance, or possibly by pur-

chase, of a share, can claim, at least approximately, that a corresponding share of the family income be allotted to him. In a *Mitakshara* joint family there is no such right. No one can claim more than that he is to be maintained, with his wife and other dependents, on a scale suited to the family's resources. Only if fraud or embezzlement or the like is alleged, will current accounts be gone into. When a partition has to be made a capital account is, of course, necessary.

Partition.—To the ancient Hindu lawgivers and commentators partition and inheritance are different aspects of the same subject, and, in fact, in their view partition was the dominant aspect. This was because a Hindu ought to have at least one male agnate descendant, obtained in the last resort by adoption, and therefore ought to die a member of a joint family, if governed by the *Mitakshara*. And, even under the *Daya Bhaga*, when two or more sons succeed their father, they do not get definitely marked out shares absolutely their own until they effect a partition. Partition is in theory simple enough under the *Daya Bhaga*. Each co-parcener has a known share, all that has to be done is to lay out metes and bounds in the immovable property, and to make a fair division of the movables. But when the *Mitakshara* applies the first thing to be done is to determine the share of each co-parcener. The division is made by branches. And when there is a division between a living ascendant and his descendants the ascendant gets the same share as goes to each of his sons. Thus a father and his four sons make a partition, and each gets one-fifth of the property. If any of the sons had predeceased the father, leaving sons or agnate grandsons, these latter between them take what would have been his share. If four brothers divide, whose father and other ancestors are dead, each takes one-fourth.

Ancestral and Separate Property.—In case of dispute it will be necessary under either school to decide what is, and what is not, family property. What is claimed and proved to be either self-acquired or separate property has to be excluded from the hotch-pot, and there may have to be special provisions about the right to use wells, rights of way and other things which cannot be split into parts. There is a general Act applying to the making of partitions (Act IV., of 1893). It should be added that in most provinces partitions of land assessed to land revenue are made by the revenue courts, and in those cases the joint owners often are not members of a joint family.

A father or other ascendant governed by the *Daya Bhaga* is sole owner as against his sons and other descendants, yet there are texts indicating that if he make a partition among his sons he must divide the property equally. However, he undoubtedly can make a series of gifts to his sons or other descendants, and by them dispose of the estate in very unequal portions. At the back of this anomaly is the theory that a gift needs acceptance by the donee, and actual transfer of possession, to make it complete and cognizable in law, whereas a partition does not.

If a member of a *Mitakshara* joint family obtains a partition of his share, and has then no sons or other agnate descendants, the share is his sole and separate property. But it remains "ancestral," and as soon as he has a son born to him, or adopts one, that son becomes a co-parcener in it with him, and so with all his sons born subsequent to the partition and their sons and grandsons.

Very often the question arises "Has there been a partition or not?" The answer may affect the rights of a third party to whom a member of the family purports to have transferred property. The presumption as to jointness has already been mentioned. But whether there has been a partition or not is a question to be decided on the evidence. A fully united family is joint in house, food, worship and estate. But a family can easily be joint in house and worship and yet separated in food and estate, or it can be joint in estate, and yet to some extent separated in house and in food.

On effecting a partition provision must be made for the dependents, e.g., unmarried daughters or sisters, mother whose husband is dead, and incapables. When a dependent belongs plainly to one branch of the family, and that branch does not itself split up,

the liability of course attaches to that branch, for instance one of several brothers who separate remains responsible for his own daughters. But when brothers separate who have unmarried sisters or incapable brothers, either a special assignment must be made, for instance to meet the expenses of a girl's marriage, or one member accepts responsibility and receives some sort of compensation. If it is a mother who has to be provided for, it is not uncommon under the *Mitakshara* for a part of the estate to be assigned to her. On her death it will be divided among her sons or their descendants.

As in a *Daya Bhaga* joint family each co-parcener has a definite share which descends by inheritance; when the estate of such a joint family is the subject of a partition what has to be ascertained is what portion thereof has devolved under the rules of inheritance to each present member since the death of the person who once held the whole of it. For under the *Daya Bhaga* all property goes by inheritance when its owner dies, whereas under the *Mitakshara* the rights of a co-parcener, even if he be one of two only, go by survivorship on his death. So a Hindu governed by the *Mitakshara* risks losing all chance of inheritance to the rest of the family property when he separates by partition, for as long as two or more members remain joint even their nearest relations, once separated from them by partition, cannot inherit their joint property, as survivorship precedes inheritance. Under the *Mitakshara* only separate property and self-acquired property can pass by inheritance.

Impartible Estates.—There are impartible estates. Apart from provincial legislation, which in parts of India may have enabled large landholders to entail their estates, there are many estates, mostly the residue of suppressed sovereignties or quasi-sovereignties, which are impartible by family custom. The junior members of the family are entitled to be maintained out of the estate, and may even have portions of it assigned for their maintenance, such assignments usually being revocable. When an owner of such an estate dies without descendants, and *Mitakshara* law applies, the question may arise whether the succession goes by strict primogeniture, in the sense of English law, or by a rule which first ascertains the nearest male agnates, and then among those equally nearly related gives the preference to him entitled as against the rest of this class by the rule of strict primogeniture.

Inheritance.—We now come to the rules of inheritance. Here there is a divergence of principle between the two schools. The *Mitakshara* prefers all male agnates, however remote, to any cognate, however near, except the daughter's son. And, except under the *Maharashtra* sub-school in western India, which does place some women in a more favoured position, the only women it brings in as near heirs are the widow, daughter, mother, grandmother and great-grandmother. The basis of the scheme is preference by nearness of agnate relationship. The scheme of the *Daya Bhaga* is based upon efficacy of offerings made to the deceased, in fact it holds that the heir gets the estate because he makes the offerings. No doubt the ancient rule, as Mayne surmises, was that the duty to make the offerings fell upon the person taking the estate. But, for the benefit of the priesthood, the later ecclesiastical theories of the Brahmins put all the stress upon the offerings, and said that the estate followed them. This theory brings in some cognates in preference to more remote agnates.

There are three grades of offerings, the full cake, or *Pinda*, those making it being called *Sapindas*, the offerings of crumbs made by *Sakulyas*, and the offerings of water made by *Samanodakas*. The cake offering is made for three generations, and the crumb offering for three more. A man is *Sapinda* to his sons, to their sons, and to their grandsons, as well as to his three direct ancestors. And he is *Sapinda* to the three generations in the direct male line from his *Sapinda* ancestors, paternal and maternal. Except in the case of the daughter's son, the claims of all connected with the deceased through a woman on the ground of sapindaship are rejected by the *Mitakshara* in favour of agnates however remote. But the *Daya Bhaga* admits these claims with the result, so far as the inner circle of heirs are concerned, of bringing into it sister's son, father's sister's son, and grandfather's sister's son. This inner circle includes those related to the deceased by being descended

from a common great-grandfather, or nearer relation, by agnation, and when we get beyond it the differences between the two schools become much greater, for then the *Daya Bhaga's* preference of all who offer the full cake over all who offer only crumbs, and its doctrines about mutual sapindaship, and about the effects of sapindaship to the same person, have more far-reaching effect.

Order of Inheritance.—Now as to the order of inheritance. The first heirs are sons, agnate grandsons and agnate great-grandsons. Grandsons and great-grandsons between whom and the deceased a son or grandson survives do not take directly, but representation is allowed in the case of those the links between whom and the deceased are already dead. But for this case representation is nowhere allowed in Hindu law, e.g., a brother excludes sons of deceased brothers. After the three generations of descendants come the widow, then the daughter, and then the daughter's son. Daughters' sons take *per capita*, and a living daughter excludes all sons of deceased daughters. Next come the parents, of whom the *Mitakshara* places the mother, and the *Daya Bhaga* the father, first of the two. Then brothers, sons of brothers, and agnate grandsons of brothers. Here the *Daya Bhaga* interpolates the sister's son. Then the grandparents and a like three generations from them, with the father's sister's son interpolated by the *Daya Bhaga*. Then the great-grandparents and the three generations from them. For the complications beyond this point, especially under the *Daya Bhaga*, the reader should consult the works of Mayne and Trevelyan.

Wills.—There can be no doubt at all that in its beginnings Hindu law knew nothing of wills. There is no Hindu word for a will. A legacy can be regarded as a gift to take effect after death, and according to both Hindu and Mohammedan law a gift is of no effect until the donor has transferred possession to the donee. And, when dead, the donor is no longer there to do so. But undoubtedly Hindus were struggling towards a right to bequeath in the days before British rule, especially in Bengal. There property had become individualized, for the jointness of family rights was destroyed by the doctrines of the *Daya Bhaga*. And ecclesiasticism always favours gifts and bequests for pious purposes, and Bengal law is dominated by ecclesiasticism. Reluctantly, and by progressive rulings, the supreme courts came to recognize that a Hindu can make a valid will, first in Calcutta, where an opinion was formally sought from the East India Company's Sadr court, and afterwards in Madras and Bombay. Now it is settled law that a Hindu can dispose by will of all that he can unrestrictedly alienate in his lifetime, i.e., in case of a male, of all his property under the *Daya Bhaga*, and of all his separate and self-acquired property under the *Mitakshara*, and in the case of a female of certain classes of her property. The courts felt themselves compelled to deny to a testator the right to create anything approaching a perpetuity. The limits during which final vesting can be delayed are now laid down by legislation passed in 1916. Except in the presidency towns, and in Bengal, Behar and Orissa, where the Hindu Wills Act applies, a Hindu will may be either written or nuncupative, and does not require to be attested.

Debts.—Hindu law undoubtedly recognized that debts ought to be paid, and had its methods of compelling payment. And the religious view of debt in Hinduism is that he who dies in debt suffers torment or degradation in the next life, which can be ended only by payment of the debts. We have seen that Hindu law is a branch of Hindu religious teaching. Hence we have the principle that a son or grandson is under an especial obligation to pay the debts of his father or grandfather. As, in the ordinary way, he is the heir, this is fair and equitable. It is now settled by legislation that no one, whether he take by inheritance or by survivorship, is bound to pay debts to a greater amount than the benefits he receives by the passing of the estate of the deceased. First, of course, it has to be ascertained what property the deceased left. So far as concerns the estate of a Hindu governed by the *Daya Bhaga*, or the separate or self-acquired property of one governed by the *Mitakshara*, all debts which could have been recovered from him in his lifetime rank for payment. It is when the deceased died as a co-parcener in a *Mitakshara* joint family that difficulties arise over the "pious obligation" of sons and grandsons. A debt

may have been incurred for joint family purposes, recognized as such by Hindu law. Then all the family property is liable for it. It may have been incurred for the debtor's personal purposes, and if the particular purpose of a debt was not illegal or immoral the doctrine of pious obligation will generally make all that share of the family property liable for it which on a partition would have gone to the debtor and his descendants. Or the debt may have been incurred for illegal or immoral purposes. If the creditor knew, or ought to have known, of such purposes, the family property is not liable for it at all. As the father can burden the sons by his indebtedness, if it be not due to illegality or immorality, so too he can sell or mortgage their potential shares with his, especially to pay a debt already existing. And it is decided that the creditor can implead the sons and grandsons when suing the original debtor in the latter's lifetime. The effect of failure to implead them, or of failure to state distinctly that their shares are attached when execution of a decree is taken out, has been the subject of numerous rulings of the high courts.

Alienation and Maintenance.—Originally, no doubt, a member of a *Mitakshara* joint family could not alienate his share of the property for personal purposes, until he obtained a partition. Now, not only can he do so according to rulings of the high courts at Madras and Bombay, but his personal debts can be enforced against it, provided always that a decree is obtained and attachment of the share effected during the debtor's lifetime. On his death his rights vanish, and, as they go by survivorship and not by inheritance, they cannot be followed into the hands of the survivors unless the doctrine of "pious obligation" applies to the latter.

The right of certain persons to be maintained out of family funds, or by their living agnate ancestors under the *Daya Bhaga*, has already been mentioned. But Hindu law also envisages other rights of maintenance. Quite independently of inheritance of ancestral or other property, wives, minor sons, unmarried daughters, and infirm and penurious parents must be maintained by a Hindu who has means or can work. And widows and daughters of deceased members of a *Mitakshara* joint family, and under either school of law widows of persons whose property is inherited by their sons, grandsons or great-grandsons have a definite right to maintenance. By decree of court that right can be charged upon the property, and under the *Daya Bhaga* a widow whose sons or other descendants divide up the property of their deceased father or ancestor, can claim the allotment to herself for life of a share equal to that obtained by each son. So, too, when brothers succeed to their father, and there is a widow of a predeceased brother to be maintained. In some circumstances family property can be followed into the hands of a subsequent purchaser to enforce a claim for maintenance. A widow's right to maintenance ceases on re-marriage, and any woman's ceases if she leads an immoral life.

Women's Property.—In some respects, and as regards some kinds of property, the ownership of women under Hindu law differs from that of men. These differences depend on the source from which the property is derived. If a woman has inherited property from a male, or has obtained it as a gift by her husband or as a share on partition, she does not own it in the same way as a man would do; she obtains only a kind of restricted ownership. She has the full enjoyment and management of it, but she cannot sell it, or give it away, or dispose of it by will; and at her death it goes not to her heirs but to the heirs of the person from whom she obtained it; her ownership simply comes to an end. If she obtained it by inheritance from a male it will go on her death to the heirs of that male; if as a share on partition it will be divided amongst the other sharers; if as a gift from her husband, it will go to the heirs of her husband. In those parts of western India where the *Mayukha* prevails, by exception full rights of property are given to a woman who inherits from a male who belonged to the family in which she was born, e.g., to a daughter inheriting from her father, or to a sister inheriting from her brother. On her death such property devolves as if she had been a man.

The estate of a woman who inherits only for her own life is one of the difficult problems of Hindu law. It is by no means the same as a "life estate" in English law. The woman represents the

estate. She can absolutely dispose of it for a necessity or with the next reversioner's consent. She can surrender it to the next reversioner. And a purchaser or mortgagee dealing with a woman owner is especially put to inquire into the necessity or into the real consent of the reversioner, as the case may be, and is bound to act with the very utmost of good faith, because of the habitual seclusion of women of good social standing. An alienation by a woman, not otherwise justified, is good for her lifetime, apart, of course, from fraud and the like, and a widow with power to adopt devests herself of the estate in favour of the adoptee. A woman owning an estate for life is absolute owner of savings she effects out of income, and unless she deliberately adds them to the estate they go to her heirs.

There is also *Stridhana*, the absolute property of women. The rules of schools and localities as to this vary. The chief sources of it are gifts from blood relations and gifts at marriage, besides the personal earnings of an unmarried woman. Generally *Stridhana* is at its owner's complete disposal. The rules as to the inheritance of *Stridhana* vary with the school, and even with the locality, and with the origin of the particular property. They favour women more than do the rules of inheritance to males.

Marriage.—The code of Manu enumerates eight kinds of marriage, some of which are barbaric or even savage. Four were "approved" and four "disapproved." Two only still survive, the *Brahma*, an approved form, nominally a gift of the bride by her father to the bridegroom, and, among the lower castes, the *Asura*, a disapproved form, nominally a purchase of the bride by the bridegroom. Marriages are often celebrated when both parties are very young. Many Indian statesmen are considering or proposing legislation to stop this. The essential part in a Hindu marriage is the seven steps taken together by bridegroom and bride round the sacred fire. Among the higher castes the relationships within which marriage is forbidden are extensive. The parties should not belong to the same *gotra* or large family, and they must not be related within six generations on the father's side or within, probably, five on the mother's. Marriage must be within the caste, and sometimes, by custom, within the sub-caste. Strictly speaking there is no divorce in Hindu law. But divorce is practised by many of the lower castes, and an unchaste wife forfeits all rights except that to "starving maintenance." A Hindu man may marry any number of wives, and may have any number concurrently. A Hindu woman can have only one husband, and strict Hindu law forbade the re-marriage of widows, even of virgin widows. Many of the lower castes always allowed widows to re-marry, some of them imposing conditions on such re-marriage; and by Act XV. of 1856 any Hindu widow may validly re-marry. She forfeits on re-marriage any property inherited by her from her first husband or from a predeceased son, unless she belongs to a caste which, before 1856, permitted re-marriage accompanied by retention of such property. Equally she forfeits all rights of maintenance as widow of her first husband.

By Act XXX. of 1923 amending Act III. of 1872 a Hindu man and a Hindu woman of different castes may lawfully marry. Act III. of 1872 originally provided for the marriages of persons of whom neither professed the Christian, Jewish, Mohammedan, Hindu, Jain, Sikh, Buddhist or Parsee religion. Marriages under it are monogamous, and are subject to divorce on the same grounds as are marriages between Christians. And the parties come under the rules of inheritance for Christians, and go out of a joint family, and cannot originate one.

Suttee.—The custom for a Hindu widow, especially in the higher castes, to have herself burned alive on the funeral pyre of her husband was prohibited and made an offence under Lord William Bentinck's administration in 1829. In consequence Suttee is certainly no longer customary, and educated Hindus would revolt from it. But there have been sporadic cases, even as lately as 1927. Those who help the widow to immolate herself are guilty of culpable homicide not amounting to murder, under the Indian penal code; if she is above the age of 18 years, the fact that she suffers death with her own consent then reducing the nature of the offence. If she is under 18 the offence is murder or abetment of murder, punishable even with death. The widow's

own insistence on becoming Suttee is a feature of all present-day cases.

Sonship.—In very ancient Hindu law the son would seem to have been his father's property, much as he was in ancient Roman law. In Manu eight kinds of sons are enumerated. Most of them are "sons" because at the moment of birth the woman who bore them was owned by the "father." Some are bought or self-surrendered. Now only two kinds are recognized, legitimate sons born in marriage, and adopted sons. (Adoption of daughters is mostly unknown to Hindus.) There are two extant forms of adoption, the *Dattaka* and *Kritina*. The former is used all over India. The connection between heirship and the duty of performing obsequies and ceremonials has already been noticed. To secure a Hindu's happiness hereafter the ceremonials should be carried on by his descendants for at least three generations. A grandson or a great-grandson can, however, make up for the absence of a son or grandson or both. But it is a grave misfortune for a Hindu to have no such descendants at all, so a male Hindu who has no son, agnate grandson, or agnate great-grandson may adopt a son. The adopter may be married, a bachelor, or a widower. Among the higher castes the boy must not have been invested with the sacred thread (possibly this will not apply when the child is a brother's son of the adopter, or otherwise in the family) and must be the child of a woman whom the adopting father could have married had not someone else done so. So a brother's son and a wife's sister's son are obviously eligible. And the adoption must be within the caste. The child must be willingly given by his natural parents (a boy cannot be re-adopted) so an orphan cannot be adopted.

Because of the importance of having a son, the widow of a deceased Hindu can sometimes adopt for him. Of course the condition of sonlessness must exist. Given that, in western India a widow can adopt unless her husband has forbidden her to while he was alive. In southern India she can adopt if in his lifetime he authorized her to, or if after his death his near agnate relations approve of the adoption being made. In Mithila she cannot adopt at all, and elsewhere she can adopt if in his lifetime her husband authorized her to. These are the varying interpretations of the text "Nor let a woman adopt a son without the consent of her lord." A married man who adopts does not need his wife's assent to the act, though she may become the adoptee's legal mother. Adoption removes the child entirely from his own family (except that he still cannot marry within its prohibited degrees) and makes him for all legal purposes, including inheritance from and by collaterals, the son of his adoptive father. Ceremonies are necessary, for an adoption is a religious act. Handing over by the natural parent or parents, with a sacred fire at the place, is the principal ceremony, and the absence of evidence of this would throw doubt upon the validity of an adoption, were this disputed. Among some of the lower castes even a married man can be adopted, and the rule about the mother being a possible wife of the adopting father does not hold. A son adopted to a deceased Hindu by his widow becomes the former's heir at once. If there is membership of a *Mitakshara* joint family, or if the adopting widow has succeeded to, and still possesses, her deceased husband's estate, things are simple enough. But adoptions by widows fail where their effect, if they were valid, would be to divest the estate of someone (other than the adopting widow) who holds it as heir of some deceased male, other than the person to whom it is sought to make the adoption. This rule is not a mere piece of theory, for if a son adopted dies without male issue, there may be authority to adopt one in his place, yet he may have married, in which case his widow, and not his adoptive mother, will be his heir. And an authority to adopt remains effective throughout the life of the widow to whom it is given, so long as she does not exhaust it. Cases have been known where a widow made a valid adoption more than 50 years after her husband's death.

Kritima Adoption.—The conditions stated above, other than that of sonlessness, apply in the case of *Dattaka* adoption only. The system of *Kritima* adoption is much looser. It is followed now only in Mithila, where, as we have seen, a widow never can adopt to her deceased husband. In *Kritima* adoption a sonless

man or woman can adopt a son to himself or herself. The adoptee must consent to the adoption, and must be of full age. No ceremony is required, only mutual consent. The adopter and the adoptee succeed to each other, but neither succeeds to the other's collaterals. The adoptee is not taken out of his own family. The adoptee performs the obsequies of the adopter if the latter predecease him. Any person within the caste, even for instance the adopter's brother, or his sister's son, can be adopted, and the adoptee may even be older than the adopter.

Lack of space forbids any discussion of the interesting matriarchal system of the Nairs of Malabar, and of some other castes in that part of India. The joint family is there found in its strongest form, and the only kind of adoption ever necessary is that of a daughter.

See Sir E. J. Trevelyan, *Hindu Law* (2nd ed. 1917); J. D. Mayne, *Hindu Law and Usage* (9th ed. 1922, edit. by Sir V. M. Coutts Trotter). (W. MAR.; A. SAB.)

BURMESE BUDDHIST LAW

Burmese Buddhist law, which is the body of customs and usages of the Burmese, has its sources in India, but belongs to a social system from which caste, seclusion of women, child marriage, the joint family and other features of the Hindu system are absent. It has been collected at various times in the last 700 years into books called *Dhammathats*, of which the *Manugyè Dhammathat*, compiled in A.D. 1756, overrides the others where it is clear and unambiguous. A collection of the *Dhammathats* made by a high official under the late Burmese kings has been published, with a translation, under the name of the *Kimwun Mingyi's Digest*.

Marriage is a purely civil contract, and is evidenced by the parties openly living and eating together as man and wife. A social entertainment celebrates the marriage of a youth and a maid, but is dispensed with in other cases. Consent of parents or guardians—which may be given or implied after the event—is required to the marriage of a youth under 16 or a spinster under 20. Monogamy prevails, but polygamy is legal; polyandry is unknown. Husband and wife are joint owners of all property acquired by their joint efforts during marriage, and of the profits of separate property brought by either to the marriage. The last may in time become merged in the joint estate. Hence it is usual for husband and wife to execute business documents together and to be joined together in litigation. In recent times there are legislation and rulings of court relating to the marriage of Burmese Buddhists with people of other races and religions.

Divorce is by *bona fide* mutual consent, as a rule before elders, including openly living apart as no longer husband and wife. Divorce can also be had by decree of court on such grounds as cruelty, desertion, or adultery of the wife. In the former case the parties, generally speaking, divide the property with reference to their rights in it during coverture; in the latter case the guilty party is more or less severely mulcted. Generally also, children inherit from the parent whom they follow and not from the other.

Any married couple, or anyone who has attained majority, may adopt one or more sons and daughters, whether already related to them or not, who on adoption sever all rights in their natural family and become co-heirs with the children, if any, of their adoptive parent or parents. To stop vexatious and expensive litigation between rightful heirs and others claiming to have been so adopted, the Burmese legislative council passed an Act in 1926 (not to come into force till notified) declaring that no dispute as to the rights of any person to inherit as or through an adopted child shall be entertained by any court unless the fact of the adoption is evidenced by an instrument executed, attested and registered as required by the Act.

Succession and Inheritance.—The estate of a deceased person devolves upon those entitled to it under Burmese Buddhist law. It follows that a Burmese cannot make a will. On the death of one spouse, the rule is that the surviving spouse takes the whole of the property absolutely. But an *orasa* child, i.e., first-born child who is of age and competent to assist in the family affairs, can claim one-fourth from the surviving parent of the opposite sex, i.e., from his mother if the *orasa* is a son, and from her father if a daughter. Also, if the surviving parent re-marries, the children

can claim a one-half partition, and this right survives, with modification, against the step-parent if the natural parent dies.

If the deceased was not married at death, the main principles are that the inheritance shall not ascend when it can descend; that it shall not ascend more than is necessary; and that the nearer excludes the more remote. Hence, children come first, sharing equally; failing them, grandchildren; failing direct descendants, brothers and sisters; and next in order, parents, grandparents, nephews and nieces, uncles and aunts, grandnephews and nieces, cousins and so on. Where the heirs are children, and offspring of deceased children, such offspring divide among them what would have been their parent's share if he was the *orasa*, otherwise one-fourth only of their parent's share if he or she had lived to inherit, the remaining three-fourths reverting to the estate. Where only grandchildren, born of different children, are left, the whole body divide the estate equally *per capita*, e.g., ten of such secure each one-tenth of the estate. It is possible here to give a few examples only; for a fuller discussion, and for the subject of Burmese Buddhist law generally, see S. C. Lahiri, *Principles of Modern Burmese Buddhist Law* (2nd ed. 1927).

(A. Mr.)

MOHAMMEDAN LAW

To Mohammedans much of Mohammedan law is at least as sacred as are the texts of the *Shastras* to Hindus. The sources of Mohammedan law, its growth and progress, and how it has come to divide into two schools and some sub-schools are set out in the article discussing ISLAMIC LAW (*q.v.*). For Sunni Muslims the Koran, the traditions (*Hádith*), the agreement of those who had known the Prophet (or possibly the agreement of the body of the faithful) (*Ijmá'a*) and analogy (*Qiyás*) are the sources of law, but the Hanafites use *Qiyás* more freely than do the others. The school of Sháfei has followers in India to an appreciable number, but the vast majority of Indian Sunnis are Hanafites, followers of Málík and Hanbal scarcely existing in the country. There were commentaries or digests well known in India, called the *Hidáya* and the *Fatáwa Alamgiri*. A translation of the former by Hamilton, and Neill Baillie's work based on the latter, were the only books in English to which the courts could resort for guidance on Mohammedan law for some considerable time.

Succession.—The Sunnis and the Shíahs differ widely as to the law of succession, this much being common to both, that the ordinarily bequeathable portion of a person's estate is one-third, the rest going by the law of inheritance. Shíah law will be treated of later, at present our concern is with the Hanafi law of inheritance. There are three primary classes of heirs, who in current usage are loosely spoken of as sharers, residuaries, and distant kindred. Sharers are those who are mentioned in the Koran as entitled to shares. Residuaries are male agnates who are not sharers (some are both sharers and residuaries) and the full and consanguine sisters. Distant kindred are all blood relations neither sharers nor residuaries. Sharers have the first claim on the estate, subject to this, that some sharers are liable to be completely ousted by some residuaries. The shares of some sharers vary according to circumstances. Other sharers, e.g., grandparents, daughters of sons, and sisters, can be excluded by the mere existence of nearer relations. The Prophet almost certainly modified the pre-existing Arabian customs by giving a right of inheritance to many women. The sharers are: husband $\frac{1}{2}$ or $\frac{1}{4}$, wife or wives $\frac{1}{4}$ or $\frac{1}{8}$, daughter $\frac{1}{2}$, daughters $\frac{2}{3}$ (son's daughter or daughters replacing daughters if there be none), father $\frac{1}{2}$, mother $\frac{1}{4}$ or $\frac{1}{8}$, full sister $\frac{1}{2}$, full sisters $\frac{2}{3}$ (in their absence consanguine sister $\frac{1}{2}$, consanguine sisters $\frac{2}{3}$), uterine brother or sister $\frac{1}{2}$, uterine brethren $\frac{1}{2}$, true grandfather $\frac{1}{2}$, true grandmother $\frac{1}{4}$. A "true" grandfather is an ancestor in the direct male line, and a "true" grandmother is an ancestress between whom and the deceased there is no "false" grandfather. Thus both actual grandmothers are "true," as are three great-grandmothers and four great-great-grandmothers. "How high soever" and "how low soever" are technical terms of Mohammedan law, "father's father how high soever" being the same as "true grandfather." "Son's son how low soever" means a male agnate descendant. "Child of a son how low soever" means a child of a son or of a male agnate descendant. "Consanguine"

means "related through the father only" and "uterine" means "related through the mother only."

The share of either spouse is on the lower level if there be a child or a child of a son h.l.s. The share of the mother is on the lower scale if there be a child or a child of a son h.l.s., or two or more brothers or sisters. It is also subject to diminution when the heirs are father, mother, and a spouse, in order to give the mother half what the father gets, according to the rule of "double share to the male." A daughter or daughters become "residuaries with their brother or brothers" when there is a son or sons. A son (or son of a son h.l.s. of higher rank than herself), or two daughters, exclude a daughter of a son h.l.s. If there be merely a daughter and a daughter of a son, the former gets $\frac{1}{2}$ and the latter $\frac{2}{3}$, i.e., $\frac{1}{6}$. Full sister is excluded as sharer by a child or a child of a son h.l.s. and by father and true grandfather, and, when there is a full brother or brothers who take as residuaries, is residuary with them. Consanguine sister bears much the same relative position to full sister as son's daughter does to daughter. Full sister is not excluded as sharer by consanguine brother, but, of course, consanguine sister is, though she may be residuary with him. True grandfather is excluded by father, and true grandmother by mother, by nearer true grandmother, or by any heir in the line between her and the deceased. Uterine brethren are excluded by all who exclude full sister from being a sharer.

Residuaries.—If there be sharers who by the application of these rules would get the whole estate, the residuaries get nothing. If the sharers are entitled to take more than exhausts the estate (e.g., wife $\frac{1}{2}$, two daughters $\frac{2}{3}$, father $\frac{1}{2}$, mother $\frac{1}{4}$, total $\frac{3}{4}$) the shares are diminished proportionately. If there be a surplus and there are residuaries the latter get it, but in such case if there be no residuaries the sharers, other than the spouses, divide it proportionately.

As noted, residuaries, if there be any, take what is left. They are those who, in addition to father and true grandfather, would have had a right of inheritance under pre-Islamic Arabian custom, and in some instances the Prophet gave their sisters a right of inheritance along with them. First come sons, with daughters, each son taking twice as much as each daughter. Then, if there be no sons, sons of sons with daughters of sons, each son of a son taking twice as much as each daughter of a son, there being no division *per stirpes*. Then agnate great-grandchildren in the same way. A son excludes all grandchildren and a son's son excludes all great-grandchildren. After agnate descendants comes the father. Then the true grandfather, with brothers and sisters. One section of Hanafites allows true grandfather to exclude brothers and sisters entirely. Another brings him in with full (or in default of full with consanguine) brothers and sisters under rules which give the grandfather some advantage in certain cases. Full brother excludes consanguine brothers and sisters. Sisters, full or consanguine, come in with brothers of their own kind, each brother getting twice the share of each sister. These sisters are the last female residuaries. Then come sons of full brothers, then sons of consanguine brothers, then agnate grandsons of full brothers, and then agnate grandsons of consanguine brothers, and so on to each generation of the descendants of the deceased's father.

The nearer excludes the more remote, and the full blood, other things being equal, is preferred to the half. Similarly with the agnate descendants of the deceased's father's father till they are exhausted, and then similarly with those of the deceased's father's father's father, and so on, as long as any agnates can be traced. Exceptionally full sister or consanguine sister can take as a residuary though she have no brother living. This is when daughters have taken the $\frac{2}{3}$ "allotted to women" and the nearest residuaries come later in order than true grandfather, e.g., nephew, uncle, or more distant relations. Then the full sister, or in default of her the consanguine sister, comes in in place of brother.

Lack of space forbids discussion of the rules applying to distant kindred. Distribution between them has been elaborately discussed by Muslim jurists, even the case being imagined where the heirs are cognate great-great-great-grandchildren, all the links between whom and the *propositus* had pre-deceased him. But descendants have a preference, and, other things being equal, one

who is the child of a possible sharer or of a possible residuary has preference over others.

An infidel, whether by birth or by apostasy, cannot inherit from a Muslim under strict Mohammedan law, but that bar is removed in India by Act XXI. of 1850. Hanafi law forbids a person to inherit from one whom he has killed, even when the killing was by accident or misadventure.

Wills.—Some power of bequest seems always to have been recognized by Mohammedan lawyers, but it extends, ordinarily, only to one-third of the estate as remaining after payment of debts and funeral expenses. But, after the succession has opened, the heirs may validate a bequest or bequests exceeding one-third. A bequest to an "heir," *i.e.*, to one who on the death of the testator happens to be entitled as a sharer or as a residuary, is void unless similarly validated by the other heirs. There are rules about the abatement, proportionately or otherwise, of legacies which between them exceed the disposable one-third. Preference is given to those for pious purposes mentioned in the Koran. Gifts made in what is called "illness of death" are on nearly the same footing as bequests, as are purchases or sales made during such an illness on terms actually intended to confer an advantage on the other party out of the dying person's estate, as, for instance, the sale of property for half its real value. But acknowledgments of a debt in "illness of death" are good, even in the absence of all other evidence of the debt, except when such acknowledgment is in favour of an heir, when it is void. And debts of which there is other evidence have the preference, if the estate is insufficient to meet all.

A will may be in any form, written or oral, and, if written, need not be attested. A *Wasi*, who is in much the position of an English executor, may be appointed by a testator. In default of there being a *Wasi* the estate vests at once in the heirs. But, optionally, probate of a will, or letters of administration, or a certificate to collect debts on succession, may be applied for to a court having jurisdiction.

Fictitious Relationship.—Ancient Mohammedan law allowed the creation of fictitious relationship, principally when a tribesman stood surety to his tribe for the behaviour of a refugee from another tribe. This is obsolete in India. Therefore the courts in India do not have to take account of what Muslim lawyers designate "the residuary for special cause." But, by custom, Mohammedans in many villages in the Punjab can adopt, as Hindus can. And, equally by custom, in the Punjab and elsewhere women are often excluded from succession, contrary to strict Mohammedan law. When slavery existed the acknowledgment by a master of the paternity of a child born to one of his female slaves was a matter carrying considerable legal consequences. Nowadays if the child of a maidservant were so acknowledged the courts might have to consider the legal effects, if any.

Marriage is essentially a civil contract in Mohammedan law, based upon the consent of the parties, or of those entitled or authorized to represent them. Certain legal results must follow from a marriage, but as to other incidents the parties have some freedom in fixing the terms of the marriage contract. For a minor, *i.e.*, a person under puberty, a "guardian for marriage" is necessary. The preferable guardian for marriage is the father (or father's father *h.h.s.*). A marriage at which he is such guardian is final and complete as regards his ward. But when by reason of the death or unavoidable absence of the father or grandfather another guardian for marriage acts, the ward, whether husband or wife, can repudiate the contract on attaining puberty. But once it has been explicitly or implicitly ratified after attaining puberty there can be no repudiation. There can also be an "agent for marriage." He is a person commissioned either to marry for his principal a certain definite person as husband (or wife) or to find and marry for his principal a suitable husband (or wife). The principal can make the discretion left to the agent as narrow or as wide as he chooses. But to enable the agent to contract with himself or herself, or with his or her ward, as spouse for the principal, direct and unequivocal permission to do so must have been conveyed by the principal. And an agent generally empowered cannot marry a woman client to a social inferior, and

cannot render a male client liable for more than suitable dower. But if it be no transgressing of his authority, he can marry his client A, a man, to his client Z, a woman, taking the place of each party in the contract. A marriage must take place in the presence of Muslim witnesses, two men, or one man and two women. The parties must say words by which it is made clear that they agree that a marriage between them is called into being from that moment. And the first speaker's proposal (which may be in the form "I have married thee") must be answered and assented to practically then and there, "at the same meeting" as it is called, by the other party.

Bars to Marriage.—Marriage is forbidden, on grounds of consanguinity, with ascendants, descendants, brother and sister and their descendants, and brothers and sisters of ascendants. It is forbidden on grounds of affinity with ascendants and descendants of a present or former spouse, and with any person who has been the spouse of an ascendant or descendant. There can, in some circumstances, be a bar through fosterage. A woman can have only one husband at a time, but a man can have four wives at any one time. So a man's marriage may be void by reason of "unlawful conjunction," *i.e.*, because the wife married makes a fifth, or because she is too nearly related to one of his existing wives. For a man may not simultaneously be husband of two women so related to one another, that if one of them was a man they could not marry each other. This does not of necessity prohibit marriage with the second when the first has died or been divorced. A Muslim's wife must be a Muslim or a *kitābia*, *i.e.*, a Jewess, or a Christian, or (possibly) a Zoroastrian. A Muslim's husband must be a Muslim. A marriage may be voidable, and not flagrantly void, in which case children born of it before a court pronounces against it are legitimate.

Divorce.—A Mohammedan husband may divorce his wife, or any of his wives, at any time, and he cannot divest himself of this right. The approved method of this divorce, or *tālāk*, is a pronouncement of divorce (which, if not repeated, is not immediately effective) followed by abstinence from marital relations for three of the wife's periods. A second and a third pronouncement can be made at suitable intervals. Until either three pronouncements have been made, or the three periods have run out, the divorce is revocable at the husband's option, and he can revoke it (thus wiping out any pronouncement or two pronouncements already made) either explicitly or by renewal of marital relations, and the wife is not entitled to any say in such matter of revocation. But the three pronouncements may be made at any shorter intervals, even in one breath, so to speak, and though this is disapproved, a divorce so made is at once irrevocable, and takes effect when the *iddat* or three periods has elapsed. The *iddat* lasts until delivery if there be a pregnancy. The divorced couple are free to marry again when the divorce takes effect, and can re-marry one another, unless the divorce has been triple, in which case such a re-marriage cannot take place unless the wife has in the meantime been the wife of some other man. The check on this power of a husband to divorce his wife is in practice the fact that he generally owes her a good part of her dower, and that that becomes payable to her as soon as the divorce takes effect.

There can also be a divorce by reason of imprecation followed by cessation of marital relations, or by reason of accusation of the wife of adultery by the husband on oath, denied by her on oath. A husband can empower an agent to divorce his wife for him, and can limit the agent's power, *e.g.*, to one pronouncement only, and can make the wife herself such agent. Such power is sometimes exacted by the wife in the marriage contract, for use if the husband takes a second wife. There can, of course, be divorce by mutual consent on whatever reasonable terms, as to money or otherwise, the parties may agree to.

Dower.—Payment by the husband to the wife of a sum of money, or other lawful and material consideration, as her dower is a necessary feature of a Mohammedan marriage. The dower must not be below a certain small minimum, and either is fixed when the contract is made, or is the "proper" dower appropriate to a woman of the family and social position of the wife. It may be wholly "prompt" or wholly "deferred," or partly the one and

partly the other. Prompt dower is payable at once, and the wife may refuse to enter upon marital relations till it is paid, but having entered upon them cannot refuse to continue them because it remains unpaid. Deferred dower is payable at the husband's option at any time during the marriage, and if not paid during it becomes payable on divorce or on the death of either party. It must be remembered, in the case of the wife's death, that though her husband will be one of her heirs, yet her parents, if they survive her, will also be among her heirs, even if she has left children. A wife is legally quite independent of her husband. She can sue him for prompt dower, or for anything else he owes her, and he is not liable for her debts incurred outside her reasonable maintenance, or for her torts.

Pre-emption is not mentioned in the Koran, but this "right to acquire by compulsory purchase, in certain cases, immovable property in preference to all other persons" (as defined in Wilson's *Anglo-Mohammedan Law*) is undoubtedly a part of Mohammedan law. The possible pre-emptors in order of preference are (a) co-sharers in the property part of which is sold, (b) persons who own a property to which the property sold is servient in respect of an easement, or a property which is jointly dominant with the property sold over some third property in respect of an easement, and (c) owners of contiguous property, unless the estates be large. The pre-emptor is required by Hanafi law to make a demand of pre-emption immediately upon hearing of the sale, and then, without unreasonable delay, to repeat the demand in the presence of two witnesses to the vendor, or to the vendee, or on the property, stating simultaneously that he has made the first demand. By custom a right of pre-emption has attached to sales of immovable property in various districts, towns and villages, and Hindus and others are then subject to it as well as Muslims. The law of pre-emption has been codified into Acts in the Punjab, the North-West Frontier Province, Oudh and Agra. Pre-emption is recognized to prevail in parts of Behar and Gujarat. It is not recognized at all in the greater part of the presidency of Madras.

Schools Other Than That of Hanifa.—Sir W. Markby in contributing to earlier editions of the *Encyclopædia Britannica*, noted that "Mohammedan law as applied to any Mohammedans except those of the Hanafite school has as yet been comparatively little studied by modern lawyers." But since he wrote, the writings of French administrators and judges on Málíki law have become available by Major Ruxton's translation for use in Nigeria (*Málíki Law*), and Van den Bergh's rendering of Nawáwí's *Minhá-j-ut-Tálibín*, used in the Dutch Indies, has been put into English by Howard, a judge in the Straits Settlements. This last is the standard work of the school of Sháfeí. Similarly Ameer Ali's work on *Mohammedan Law* has set out Shiah law in equal fulness with Hanafi law. There are many Shiahs in India, especially in Oudh, though Sunnis very much outnumber them.

Inheritance Under Shiah Law.—The Shiah law of inheritance differs much from that of the Sunnis. The sharers and their shares are found unaltered, for the Koran prescribes them. But agnates and cognates rank together as heirs, so "residuary" and "distant kindred" disappear. Apart from husband and wife, the Shiahs arrange all heirs in three classes: (1) parents and descendants, (2) ancestors, brothers, sisters and descendants of brothers and sisters, and (3) all other relations. Any person in the first class entirely excludes all in the second, and any in the second entirely excludes all in the third. It will be seen that brother and sister are entirely excluded by either parent, or by any descendant agnate or cognate, but under the Hanafite system mothers need not entirely exclude them, and they themselves entirely exclude all descendants of daughters. Also the nearer excludes the more remote, and no one can take between whom and the deceased a living link survives. So a daughter will exclude all descendants of sons or daughters, both male and female. And there is some representation. If the heirs be the descendants of two deceased sons and of two deceased daughters, then $\frac{1}{4}$ is allotted to the children of each son, and $\frac{1}{4}$ to those of each daughter, and distribution is made again on the principle of the double share to each male among each of these four groups of grandchildren of the deceased. If the heirs are great-grandchildren the process is carried a step

further. If there are parents and descendants (any descendant, agnate or cognate, diminishing the mother's share under Shiah law), in imagination the sons and daughters who have left descendants are restored to life, if there be no living sons or daughters, in order to see how the distribution is to be made.

With the second class the governing rule (subject to possible exception by reason of a single uterine brother's or sister's share being only $\frac{1}{2}$) is $\frac{2}{3}$ to the father's side, and $\frac{1}{3}$ to the mother's. And the nearest ancestor ranks with, and as if he or she were, the nearest brother, sister, or descendant of a brother or sister; e.g., mother's father would come in with uterine brother, or uterine brother's son. There is a similar governing rule for the third class. The rule that the nearer excludes the more remote applies always to the second and third classes as well as to the first, and full blood excludes equally near consanguine half-blood. Space does not permit of a full exposition of this interesting scheme of inheritance. If the only persons entitled to inherit (and the rule of exclusion by classes must be remembered) be sharers, and their shares do not exhaust the estate, the surplus is divided proportionately among them. But if the shares more than exhaust the estate, then, in the first class, daughters must bear all the loss. Bequests to an heir or heirs, if they come within the disposable third, do not need the consent of the other heirs, and any bequests exceeding the third can be validated by the heirs not only after the inheritance opens, but even in the testator's lifetime.

Shiah Marriage.—The most notable difference between Sunni law and Shiah law in the matter of marriage is that the latter permits temporary marriage. Husband and wife can agree to marry for any time, say for an hour, or for a millenium. If both are alive when the time specified runs out, the marriage then terminates automatically, but it can be renewed by the consent of both. There must be a proper dower when a temporary marriage is entered into. A husband may have as many temporary wives as he chooses. A husband cannot divorce a temporary wife by *tálák*, so among people of position "temporary" marriages for 100 years are not unknown, as they secure the wife against the indignity of being divorced. But the husband can virtually terminate the marriage by making the wife "a gift of the rest of the term." For marriages generally the presence of two witnesses at the making of the contract is not so absolutely necessary as it is with the Sunnis, and possibly among at least some Shiahs something in the nature of a religious ceremony should be added to the civil agreement. Some Shiahs, it appears, would prohibit the marriage of a Muslim man with any non-Muslim woman, and some would go so far as to prohibit marriages between Shiahs and non-Shiahs, especially when the Shiah party is a woman. But the restriction against the marriage of a Shiah man with a non-Shiah or non-Muslim woman does not apply if the marriage is a temporary one.

Shiah Pre-emption.—Shiahs allow no right to pre-empt because of vicinage, and regarding easements, allow such a claim only in one complicated and unusual case. And if there are already three or more co-sharers in the property there is no right of pre-emption on the ground of co-ownership, at least according to some Shiah sub-schools. The two demands which Sunni law requires are not necessary, for with the Shiahs the pre-emptor must merely make his claim to those interested with due diligence, upon hearing of the sale.

See M. Nawawi, *Minhaj et Talibin*, trans. from ed. of L. W. C. van den Bergh by E. C. Howard (1914); Syed Ameer Ali, *Mohammedan Law* (4th ed. 1917); Sir R. K. Wilson, *Anglo-Mohammedan Law* (5th ed. 1921, rev. by A. A. Yusuf Ali). (A. SAB.)

INDIAN LITERATURE. In Europe literature is, as regards its subjects, largely international, and any new fashion, such as romanticism, pessimism, the psychological novel, the detective novel, is quickly propagated. The individual qualities of prominent writers are soon known, directly or through translations, and evoke responses more or less obvious. Moreover, the similarity of social conditions and outlook lends interest to the same problems everywhere, and international science causes them to be approached from the same points of view.

In India the bulk of the educated public is acquainted with English; new English publications are quickly available in the

libraries and reading-rooms; any new book which has obtained a vogue in England will soon be reviewed in India and be a subject of articles in magazines. Moreover, India has in England, America, France, Germany and elsewhere numerous students, and some journalists, who are living the lives of those countries. Consequently, there is a very large output of writings which in spirit and manner, and often in subject, are not properly Indian, but either international or what may be termed "colonial." In Bengal alone over 1,000 publications in English (irrespective of bilinguals) are produced annually, and there are over 100 English periodicals of different kinds. We might mention in addition the large number of works by Indians and officials or ex-officials in India which are actually published in England.

A second department of Indian literature consists of writings in Indian languages which are based upon European models or deeply affected by such. Here we have a great mass of fiction, biography, history, much drama, lyric poetry, travels, political and social pamphleteering and an immense magazine literature, modes which are simply copied from European models. In this sphere we should not overlook the considerable number of actual translations or adaptations of individual works in English, French and so forth. This might be described as the vernacular literature of absorption.

A third stage is represented by that vernacular literature which, while it has absorbed European influences, has yet recovered an Indian outlook and temper, whether in the course of nature or in obedience to the strong reactionary feeling. Already in the '80s of the 19th century Bengal had produced a novelist, Bankim Chandra Chatterjee, whose work exhibits a creative synthesis of the new and the old; and at the present day the Bengālī language has, irrespective of its outstanding representative, Sir Rabindranath Tagore, a modern literature conscious of an independent inspiration.

A fourth department is constituted by the continuance of ancient modes and conceptions.

Linguistic Distribution.—Apart from the influence of particular centres, such as universities, the literature is very unevenly distributed. The matter must be stated in terms of languages. In the field of Assamese, Oriya, Bihārī, Panjābī, Sindhī, Nepālī and Kāshmīrī, the Rājasthānī dialects and Malayālam of southern India, the old modes may be said to prevail with little innovation. High Hindī, in regard to which the same might have been said a few years ago, is rapidly equipping itself with literary and scientific compositions on modern lines. Urdū, the chief organ of Mohammedans in Hindustan, the Punjāb and Central India, is further advanced in the same direction. The two chief languages of the Bombay Presidency, Gujarātī and Marāṭhī, more especially the former, have a considerable modernizing literature. The Telugu of Madras is perhaps not so far advanced; but Tamil has a large productivity, hardly second to Bengālī. Special educational efforts have led to the publication of a fair number of manuals in Kanarese (Mysore), as also in Gujarātī (Baroda) and Urdū (Bhopal and Hyderabad); but other Indian States are not productive on modern lines.

For publications in English about the same proportions hold as for modernized vernacular literature. English works are, indeed, far more prevalent in the provincial capitals, whereas those in the vernacular abound in the less anglicized districts, Gujarātī, for instance, favouring Ahmadābād, Marāṭhī Poona. The non-modernized literature is also published in all considerable places.

The chief classical language of India, Sanskrit, is represented by editions of two kinds, those on old Indian lines with or without commentaries in Sanskrit or in modern vernaculars, and those with commentaries in English. The former are very widely published in the Deva-nāgarī character, or in Bengālī, or in Gujarātī or in the south Indian alphabets, sometimes even in the Panjābī or Urdū; and there are various combinations of these scripts. Editions on European lines appear for the most part in the provincial or State capitals or in the university towns. New original works in Sanskrit are not infrequent in the sphere of oriental philosophy, philology, science and religion; occasionally there appear new poems and dramas of considerable extent

and literary merit; and there are also Sanskrit periodicals, including even a newspaper.

Other classical languages are: (1) Prakrit, usually that of the Jains and published in the Bombay province or in the Hindī- or Mārwarī-speaking areas; (2) the Buddhist Pāli, rare in India; (3) the Tibetan, published at Calcutta and Darjeeling; (4) the Pahlavī of the Parsees, published in Pahlavī or Gujarātī script in the Bombay Presidency; (5) the Arabic, appearing chiefly in Delhi, Lucknow, Hyderabad; (6) the Persian, more occasional. Many of the vernacular languages also have their old or classical periods, and prominently the Dravidian group, Tamil, Telugu, Kanarese and Malayālam; re-editions of their classical works are very frequent, and for the most part are published within the areas of the respective vernaculars.

Translations of Sanskrit works are innumerable in nearly all the vernaculars, the *Bhagavad-gītā* for instance being reproduced many times every year; and some degree of the same favour extends to some of the local classics, the Hindī poems of Tulasī-dāsa, and the Hindī *Bhaktamāla*. Among modern Hindu writers Swāmī Vivekānanda, Bankim Chandra Chatterjee, Sir Rabindranāth Tagore, Romesh Chunder Dutt and Haraprasād Shāstrī have also a vogue in several languages; and popular novels, in particular the favourite *Chandrakāntā* (from the Hindī), and its imitators, are frequently translated. Portuguese publications appear at Goa, French at Pondicherry and Chandernagore; the Roman Catholic missions print some brochures in Latin, and there is even an Italian periodical issued from Mangalore (*La Missione di Mangalore*).

The literature of India is, therefore, highly polyglot, while individual publications are very often bilingual at least. The alphabetic aspect of the matter has also been partly indicated. In spite of the attention which has been given to the possibility of a common script for India, some advocating the Roman, some the Deva-nāgarī (which has a Hindī periodical devoted to its interest), there is no evidence of progress toward simplification; there is a certain amount of Roman-Urdū, and Roman is usually employed for the Konkani form of Marāṭhī and for the rendering of previously unwritten languages. But in general each leading language holds to its traditional script. Sometimes it has more than one; for the Mohammedan writes his Panjābī or Hindī or Malayālam or Tamil (not, however, his "Musalmānī-Bengālī") in the Urdū character, with any necessary modifications. The Sikh may write his Sindhī in the Gurumukhī of the Punjāb. Bilingual books are therefore usually also bilingual (except as regards the above-mentioned case of the Sanskrit, or similar cases with Pahlavī and Gujarātī, or Arabic texts with Persian or Urdū); and this adds to the multiform appearance of the Indian literary output, already sufficiently variegated, even if we overlook such characters as the Multānī, Modī, Kaithī, Savara, which indeed are rarely printed, or the numerous old writings appearing in philological works. The format of the book is not seldom that of the old Indian *pothī*, sometimes (in Bengal) even printed on palm leaves; while the Punjāb Gurumukhī and the Mohammedan Arabic are much less often printed than lithographed from handwritten originals.

Popular Literature.—To begin with the lowest stratum, we must note the existence in India of an extensive, really popular, literature in verse. In all parts of India, but especially perhaps in the Punjāb, in the Kanarese country and in the Tamil area, there is a constant production of songs and ballads, provoked by any notable occasion, such as a prize-fight, a flood or calamity, a crime, a tragedy, a personality, a social event, an act of administration; these have a real, though probably in general a brief, life upon the lips of the people, who sing them over their work or in their social gatherings. Of late years this form has been largely used for political propaganda, innumerable small collections of "national songs" appearing in all the chief languages. There are also many collections of songs for special occasions; *Garbhī* songs for women, marriage songs, songs for the Holī (spring) festival and other celebrations, boat songs for aquatic sports in Orissa and Bengal and so forth. At certain times of the year the Mohammedans put forth vast quantities of "verses"

in honour of Mohammed or dirges for Hasan and Husain. Religion has a large share in this poetic activity: songs in honour of Kṛishṇa (especially in Hindustan, Bengāl and Orissa, but also in Gujarāt and southern India), of Caitanya (*kīrtans* in Bengāl), of Kārttikeya, Ganeśa, Dattātreyā, Vithobā (in the Marāṭhī area); songs for pilgrims to or at the various shrines (innumerable in the Telugu and Tamil country); songs for temple rites; collections of Jain hymns; and the many publications of Christian sects, which in some cases (Roman Catholic) even deign to follow Indian models. Not all this popular literature is in verse, since there are occasions when sacred stories in prose (*Hari-kathās* and the like) are narrated in or near the temples.

An oral existence appertains also to a good part of the various classical writings of India. This is the case not only with Sanskrit works such as the Mahābhārata and Rāmāyaṇa, some parts of the Purāṇas, and some stories such as those of Sāvitrī and Hrishchandra, but also with the classics of the several vernaculars. Not to mention the substance of stories and legends, the texts of such poets as Kabīr and Tulasī-dāsa in the Hindī area; Vidyāpati, Govind Dās and many others in Bengāl; Narsinh Mehta, Mīrā Bāi and Prēmānand in Gujarātī; Nāmdēv and Tukārām in the Marāṭhī country, Lallā in Kashmir; the Sūfī poets of Sindh; the Vaiṣṇava and Śaiva saints and moralists of the Tamil country, are very familiar on the lips of ordinary people in their respective areas, and, besides being used in education, are frequently re-edited. In the Punjāb some parts of the Sikh *Granth* are similarly used.

On the borderland between the oral and the literary we have the drama. In India it was indigenous in many forms, from the heroic down to the morality, miracle play, the farce, the shadow or puppet show. Except in the extreme south of India, it would seem that the popular forms of representation have been more or less levelled out. The ordinary play, produced chiefly in Calcutta, Bombay and Madras, is similar to the European forms—melodrama, social sketch, burlesque, problem play (the old man and the young wife, the modern young man or woman and so forth), love story: it is generally interspersed with verses, and these are often separately published for popular use. The more literary drama, still sometimes in Sanskrit, takes its subjects chiefly from old Indian poetry and legend, and is not seldom an adaptation of a particular Sanskrit work (the *Sakuntalā*, the *Mahābhārata* and *Rāmāyaṇa* or episodes therein, and so forth). The choice is to some extent affected by local celebrity, and occasionally a political application may be suspected.

The pabulum of the ordinary reader in India is furnished by the magazine, containing essays, biographies and descriptions, short stories and serials, notes and not rarely illustrations. The total output is enormous; for in addition to the diversity of languages we have to reckon with the division of the Hindus into castes with their separate interests and claims. Important castes prefer an organ (or competing organs) of their own, which, along with the ordinary magazine material, will ventilate any matters having a communal bearing. This literature, therefore, presents no ordinary problem to the bibliographer; somewhere in India it should be sedulously collected and preserved, on account of the special biographical and sociological items which it contains. Schools and colleges have their organs (usually, however, in English). The missionary agencies, including the Salvation Army, issue innumerable periodicals of all grades, both in English and in the vernacular. Trades and the business world, professions (teaching, medicine, law, astrology, and so on), and grades of official service all contribute to the mass of vernacular matter. There are further a *Hindī Punch*, a *Hindī Graphic*, a Gujarātī and Marāṭhī *Tit-Bits*, and short story magazines; music and the stage are also represented by popular periodicals. Special interests, such as the cause of women, social service, co-operation, labour, economics, business, arts and sciences, travel, boy-scouting, are similarly equipped. The chief vernaculars have usually at least one literary periodical of a fairly high type. In some cases these have flourished during long periods: the *Sentamīl* of Madras is in its 24th volume, the *Hindī Sarasvatī* in its 25th, the Bengālī *Bhārati* in its 49th, the Gujarātī *Samālochak* in its 30th, the Marāṭhī

Vividhajñānavistara in its 56th. The Urdū *Humāyūn* also is of some standing.

Modern Indian poetry, excepting translations and adaptations of old Sanskrit works and themes, is usually in the form of short lyrics issued in small volumes. Larger productions are for the most part collected works of single authors, or anthologies, or the outcome of literary Eisteddfods. In the Hindī area the ballad of old style attains a greater length, as do Tamil *Kāvya*s on classical models. The poetry is generally erotic, ethical, philosophical or religious; but the satirical and controversial, and also, as we have seen, the political, claim a place. The verse-forms are usually the traditional ones: only Bengālī, it appears, manifests original power in this direction.

Fiction on European lines is making rapid headway in India, and is supplanting the old romantic tales, at least so far as prose is concerned. The Punjāb may still reprint its *Hir* and *Ranjhā*, *Rājā Rasālu*, etc., the Sindh its *Sassi* and *Punmūn*, the Urdū language its *Laitī* and *Majmūn*, and Hindī the tales of *Bharthari* and *Gopichand*. The novel is popular both in the form of the short story and of more substantial narratives; and it reflects all the varieties of subjects which have a vogue in English, historical, social, romantic, adventurous (including the detective novel). A new feature is the translation of well-known (including English) novels into several languages and the immense vogue of such popular stories as that of the Hindī *Chandrakānta*.

Religious Literature.—Indian religious literature, in so far as it is not lyrical, philosophical, argumentative or philological, consists mainly of manuals of ritual for daily life (*dīna-caryā*) or for particular occasions (marriage, burial, times and seasons, pilgrimages, vows), and of the stories therewith associated; for instance, the story of the Tulasī plant and that of Satya-Nārāyaṇa are constantly reproduced. Benares takes a prominent part in such publications. Since each section, from the Vedic *Sākhās* downwards, must have its separate rituals, it results that the number of such publications is very great.

We pass to a consideration of the activity in the reproduction of old canonical texts, with or without commentaries, for the purpose not of ritual, but of study and edification. This accounts for a great mass of republication: in the Punjāb, for instance, there is a steady stream of thick volumes of *Selections from the Aḍi-granth*. There are some valuable series of such canonical texts; the Jains have several, and the Madhva doctrine of south India and the sect of the Mahārājas in Bombay have thus made accessible their chief writings. Important groups have usually one or more periodical organs, which, amid other matter, publish and comment upon their authoritative books. Many religious texts are, of course, not the property of any particular sect, and are therefore variously reproduced; and from these we can hardly separate those which are of a philosophical rather than of a religious character: such are the Vedānta writings, the Madras periodical *Vedānta-dīpikāi*, and other philosophical journals; of wider scope, the *Siddhānta-dīpikāi* and the Marāṭhī *Tattvajñāna-vistara*. There are English periodicals belonging to one or the other of the above two groups: such are the *Vedānta-kesari* of Madras, the *Ahmadī Review of Religions* and *The Theosophist* (which also has vernacular allies). Modern philosophy is represented by the Calcutta Philosophical Society, and by a now extinct *Indian Philosophical Review* published during several years in Baroda.

Philology.—Philology of a more general character is no longer in India restricted to one or two classical languages, Sanskrit, Prakrit, Tamil, Pahlavī, Persian, Arabic. There are societies which devote themselves to the publication of old texts in the existing vernaculars. The Bangīya Sāhitya Parishat, with its *Patṛikā* and its series of separate old Bengālī texts, has a very honourable record. The Tamil Sangam of Madura (which issues the *Sentamīl*) is likewise distinguished. There are now other Sāhitya Parishats in the province of Bengal, and for Telugu also there is the Āndhra Sāhitya Parishat. For Hindī there are the Nāgarī-prachārīnī Sabhā and certain Mandalas; for the Punjāb the Khālsā Tract Society; in Gujarāt, where societies for publication seem to flourish, the oldest is the Gujarāt Vernacular

Society, while there is also a Sāhitya Parishat, and a Sāhitya-
vardhana Society; in Marāṭhī an important series of editions of
old poetry was published under the title *Kāvya-saṃgraha*. In
literary history there are very important and extensive works by
Rai Saheb Dineschandra Sen (Bengālī); Sir G. Grierson and
the Misra brothers (Hindī); G. M. Tripāṭhī and K. M. Jhāverī
(Gujarātī); Prof. W. B. Patwardhan (Marāṭhī); and Vīresā-
lingam Pantulu (Telugu).

As regards general philological activity of India, it is hardly
possible to draw any clear line between indigenous scholarship
and that affected by European methods; the main aim and pro-
cedure of scholarship are the same everywhere, and whether a
commentary is in Sanskrit or Bengālī or English seems to make
little essential difference. Only comparative philology is new to
India. This philological activity, wherewith is associated the
investigation of archaeology and pre-British history, and from
which we may exclude the astounding output of educational
work up to the level of university textbooks, is connected
chiefly with organizations of some kind. The Government of India
itself maintains an Archaeological Survey, which publishes annual
reports in the several provinces and at headquarters, and splen-
did special monographs, as well as a periodical relating to Epig-
raphy (see INDIAN AND SINHALESE ART AND ARCHAEOLOGY).
This example is followed by Indian States, Mysore, Travancore,
Hyderabad, Kashmir. Several provincial Governments have pub-
lished catalogues of Sanskrit mss. (Bengal, the United Provinces,
Bombay, Madras, the Central Provinces); States, small and
great, Kashmir, Nepal, Baroda, Mysore, Travancore, Alwar,
under the title *Bibliotheca Indica* a vast collection of Sanskrit,
or Arabic texts, too, are officially edited in Bombay, Mysore,
Travancore, Kashmir, Hyderabad, Baroda.

After the Governments we may mention the universities,
colleges and libraries as active in the publication of texts and
researches (the universities of Calcutta, Madras, Lahore, the
Benares Sanskrit college, the Maharajah's college, Vizianagram,
the Bankipur public library). Important journals are issued by
societies (the Asiatic Society of Bengal, which has also published
under the title *Bibliotheca Indica* a vast collection of Sanskrit,
Arabic, Persian and Tibetan texts; the Bombay branch of the
Royal Asiatic Society, the Mythic Society of Bangalore, the
Bihar and Orissa Research Society, the Hyderabad Archaeo-
logical Society, the Bhandarkar Oriental Institute); and some,
like the *Sanskrit Research*, the *South Indian Research* and the
Jain *Purātattva*, are occasionally started independently or by
religious bodies. The books issued by authors, editors, or indi-
vidual publishers are, however, more numerous, and on the whole
the Indian publication of philological, historical and archaeo-
logical matter relating to pre-British India quite dwarfs in bulk
all that is done outside. Much is highly meritorious, and some
of it is fully equal to the best production of Europe. The monu-
mental *Linguistic Survey of India*, edited by Sir G. Grierson for
the Government of India, is now completed (see PHILOLOGY).

History and Biography.—For educational purposes and gen-
eral reading many short histories of India, of England and of
other countries are produced both in English and in the vernac-
ulars. But original research and independent judgment will be
found chiefly in the few first-hand histories of particular States
and dynasties; and with a few exceptions (such as the Marāṭha
researches of Rai Bahadur, D. B. Parasnis and the volumes of
Marāṭha records published by the Marāṭha Historical Society
of Poona; the volumes of Prof. Sarkar concerning Aurangzeb;
the biography of Jahāngīr and the *Journal of Indian History*,
published by the Allahabad university school of Indian history;
the works on south India by Prof. Kumāraswāmy Aiyangar,
Subrahmanyam Aiyar and a few others) in the works of English-
men. The valuable monographs produced in Europe or India
by Indian scholars relate for the most part to ancient times, and
are less historical than philological. Many volumes of records
and calendars in English have been published by local Govern-
ments; the gazetteers also are replete with historical informa-
tion not absorbed in formal histories; and there are several socie-
ties, the Bengal Historical Society, the Punjab Historical Society

and the United Provinces Historical Society, whose journals are
composed of original matter.

Biography, including autobiography, is now popular in India,
taking chiefly the form of short memoirs, which in the case of
princes and of important religious leaders such as Debendra
Nāth Tagore and Dayānanda Sarasvatī, may attain a consider-
able length; so also in the case of historical personages, Śivājī,
Jahāngīr and others. A very favourite form, of which there are
old examples, is the serial biography, containing lives of saints,
lives of famous women, hierarchical, dynastic and family biog-
raphies. Valuable work of this kind has been done in regard to
the Tamil and Telugu saints and poets, and the poets of Bengāl
and Gujarāt. Small volumes of "prison reminiscences" have been
published by political offenders, and the number of short "lives"
of popular heroes, such as Tilak, Gokhale and Gandhi, is be-
yond counting. The old form of biography in verse is still
favoured in relation to saintly and historical characters: naturally,
it has aims other than information and research. Many Indians,
from princes downwards, have written accounts of their travels,
whether in England, on the continent of Europe, in America or
in other countries, including the Far East. But India itself fur-
nishes rich material and occasions for travellers' experiences,
especially in connection with its shrines and pilgrimages, so that
such titles as *Bhārata-bhramāṇa* quite naturally recur.

(F. W. TH.)

INDIAN MUSIC. The music of India has a threefold inter-
est. It offers the most complete example, in theory and practice,
of melody untouched by harmony; hence, it provides a key to the
problems of ancient Greek music, which have fascinated scholars
and musicians; and it has for an Englishman the appeal that it
concerns a majority of his fellow-subjects.

Musical literature refers not seldom to the "laws of melody,"
but makes no attempt to formulate them, because European
melody is always harmonized, and it is nearly impossible to say
what part of it belongs to harmony and what to melody. From a
system innocent of harmony, like the Indian, we realize (1) that
melody swings, in the first instance, on two pivots—the vocal
tonic (*amsha*), a sort of "Ecclesiastical" Dominant, at a pitch
that varies with the mode, and the tonic in our sense of the word
supported by a drone (*kharaj*) and, secondarily, on notes related
as fourth or fifth to either of these. On this varying distance
between the two tonics depends mainly the character of the
mode (*rāg*), poignant, if the *amsha* is high, festive or placid, if
low. (2) There is a general contrast of major and minor, but the
third of the scale is no more decisive of this than the seventh,
sixth, or second; the *ethos* of the minor is not so much sad as
elaborate and reflective, and is graduated or intensified by shades
of intonation which we do not possess. (3) a melody is conceived
as lying within, or round, the tetrachord, though the second part
of it may spring to the upper octave, just as, with us, it would
adjourn to a key of contrast. (4) The motion is mainly con-
junct; intervals which strike us as odd (augmented second, or
augmented fourth) are justified as motion to or from the *amsha*.
(5) The octave contains, like ours, seven notes (it is called
saṭṭaka, a set of seven) with, possibly, an eighth or ninth as al-
ternatives, not additions. The "quartertones" (*shruti*) have been
entirely misconceived by European writers. They do not provide
a scale of 22 notes through which the voice threads its precarious
path, but are in use as increments of intervals well-known to us,
and lend them an exhilarating or pathetic colouring. (Thus, from
a tonic C, the sixth, A, will have 884 accents in one mode, 906 in
another; B flat, similarly, 996 or 1,018.) The Indians have, in
fact, preserved distinctions which we have merged by our "tem-
peraments," and now employ them for a musical purpose; just as
grammar will sometimes employ different forms (*nosco*, and *novi*;
ken, *can*, and *know*) for different meanings. (6) Melody centres
in the mode. The amateur knows a dozen of them, the pro-
fessional at least five, perhaps ten, dozen. (It is customary to
say that we have only two modes, major and minor; but for
those who consider the history and the implications of the
"Neapolitan" sixth, the "German" and "diminished" sevenths,
etc., there are more than two.) The modes are differentiated

by (a) their *amshas*, (b) the flat (*komal*) and sharp (*tivra*), or the very flat and very sharp notes (*atikomāl*, *atitivra*) and (c) the amount of transilience, i.e., whether they are of five, six or seven notes in all. The various admixture of these elements gives each mode its flavour (*rāga*), and this is emphasized by assigning the mode to a particular hour of the day or season of the year.

We conceive musical times as multiples, they as sums. We take $\frac{3}{4}$ as 3×2 , and $\frac{3}{8}$ as 3×3 ; they, as $3+1+2$ and $5+2+2$ (or $4+2+3$, or in some other way). In these three instances, to go no farther, they are representing the dactyl ($- \cup \cup$) of their prosody, and allowing for (a) different lengths of short syllable and (b) different proportions of long to short. They have dealt similarly with trochee ($- \cup$), iambic ($\cup -$) and anapaest ($\cup \cup -$). The tribach ($\cup \cup \cup$) they treat as three crotchets and a crotchet rest, thus arriving at common time, which they call "three-time." Such procedure soon becomes far too elaborate to follow out here, though, in practice, they confine themselves to only a dozen kinds of time.

But, in whatever time it may be, the essence of an Indian melody is that it employs cross rhythm. Singer and drummer converge upon a point; one sings seven bars of ten units perhaps, while the other drums ten bars of seven units; or the drummer's two hands beat different times, one $2+2+2$ and the other $3+3$; or one hand starts at the beginning and the other in the middle of the bar, in different times, and they converge half a dozen bars later. The audience appreciates such a point, and waits for it.

In the absence of harmony, grace-notes are important, to emphasize one moment as against another. The couple of dozen graces that are practised are, in principle, two—the slide (as on the violin) and the "deflect" (as produced by the tangent of a clavichord). The eminence of a performer is largely decided by his skill in these, and he uses them to accentuate the essential notes of the mode.

The chief instruments are (1) *vīna*, with three drone strings, and four fretted strings on the finger board, plucked like, and with the tone of, the guitar; (2) *sitar*, a simpler form of guitar, more easily played, with less noble tone, native to Bengal; (3) *sārangi*, an elementary violin, used for the nautsch; (4) *surnai*, a hautboy of strident tone; (5) various drums, the most important being the *tabla*, a small pair, played one by each hand; and, in the jungle (6) the *banshri*, bamboo flute, of varying size, scale and compass. Concerted music, vocal or instrumental, is rare, and is in unison. (A. H. F. S.)

INDIAN MUTINY, THE, the great revolt of the Bengal native army in 1857 which led to the transference of the government of India from the East India Company to the Crown in 1858. This mutiny, accompanied by rebellion of the population in many parts and of some of the chieftains of India, was due to many causes, some of which remain a matter of controversy to this day. Whatever were the ultimate political and psychological reasons underlying the rebellion, the increasing of the native army to implement the holding of the newly acquired territories of Oudh, the Punjab and Sind, out of all proportion to the European garrison, added to a reduction of that small garrison during the Crimean and Persian campaigns, made a mutiny possible and sufficiently attractive to catch up into its whirlwind the discontented political elements.

During the 100 years which had elapsed since the battle of Plassey, the East India Company had risen, through the crumbling of the central power of the Mogul empire, from being the mandatory of that empire for the government of certain coastal tracts, to the control of the whole of the Indian peninsula. In overcoming the various warring principalities into which the Mogul power had broken up, the instruments were largely Indian soldiers themselves, who had eagerly followed the British who were proud to lead them. A vast army modelled on the British Line,¹ and clothed to resemble it, had sprung up, with all the complicated machinery and traditions of a regular standing army. Elated at the continual success which attended the British arms,

¹Line—an organized regular army.

the martial races eagerly enlisted under the Union Jack, and served gallantly and faithfully, crossing bayonets more than once with the French and sailing as far as the Mauritius, Egypt and Java to take part in the wars against Napoleon. But ever behind this great native army marched as a hammer-head European corps, some enlisted for the service of the Company, but chiefly consisting of the British Line. The European units always bore the brunt of the hardest service. This vast native army was organized in three distinct Lines, under the presidencies of Bengal, Madras and Bombay. The native army of Bengal was by far the largest, and the three armies, in addition to the Line, had developed many local corps, regular and irregular, while the larger native states also maintained contingents under treaty, trained as a rule after the manner of the Bengal army, and officered by British officers, which enlisted in many cases the same races as furnished the Bengal Line.

The Bengal army, and indeed the whole of India, was shaken by the disasters which, for the first time, overcame the Company's forces in Afghanistan in 1841-42. In the wars with the Sikhs, 1846-49, the fighting and the nature of the foe was far more formidable than hitherto experienced; the European troops had to bear a more forward part than ever in the great battles of that war, and the prestige of the Bengal army was to some extent threatened.

Earlier Mutinies.—There had been several untoward military incidents in the 50 years preceding 1857. As early, indeed, as 1764 it had been necessary to quell mutiny by the usual oriental punishment of blowing away the offenders from the guns, when 30 sepoys (sepo, more properly *sipahi*, soldier, cf. the form *sipahi* in the French African army) were so disposed of.

In 1806 a serious mutiny was brewing in the Madras army, partly born of the over-introduction of European pattern clothes and accoutrements. In 1824, the 47th Bengal Native Infantry refused to march when it was ordered for active service in Burma, and after being somewhat severely handled by European artillery, was disbanded. In 1844 no less than seven battalions of the Bengal Army broke into open mutiny over the question of allowances when garrisoning newly acquired provinces. It was to be noticed that the sterner measures of earlier days were not taken and the corps involved for the most part remained in the service.

Discontent and Danger Signals.—But there were not wanting those who saw farther and thought harder. Lord Ellenborough often said that a general mutiny of the native army was the only real danger with which the British Empire in India was threatened. His warning was solemnly repeated by Sir Charles Napier, when Commander-in-chief, basing his warning on the many defects of the military system which had gradually crept in. General John Jacob of the Bombay Army uttered still more forcible warnings during the years immediately preceding the Mutiny. Sir Henry Lawrence, than whom no greater authority existed, frequently warned all and sundry that things were not right, and that what had occurred at Kabul might happen at Delhi.

There can be little doubt that the social reforms of Lord Dalhousie and his predecessors had disturbed many men's minds. The prohibition of *suttee* and female infanticide, the subordination of Brahmans to the ordinary criminal laws, all tended to cause bitterness and alarm. The landowning class, especially among the Mohammedans, found that British rule meant curtailment of inordinate privileges, and fair treatment for the poor, while at times British zeal for justice pressed unduly on these ancient classes.

The Greased Cartridge—the Chappattis.—To this accumulation of inflammatory material, a spark was put in 1857 by strange but intelligible oversight on the part of the authorities responsible for the manufacture of ammunition. The use of the Minie or Enfield rifle involved a cartridge with a heavily greased patch at the end. The use of the cartridge for muzzle loading muskets had always demanded the biting of the end and the pouring of the powder thus released into the barrel. Then occurred an altercation at Dumdum, between a high-class Bengal sepoy and a low-caste employé of the arsenal, and the hurling of a gibe by the latter as to the utter defilement involved in the use of the

new cartridge. The news spread like wild-fire. Officers, as soon as they heard of the trouble, took the matter up, and whatever material had been used, clarified butter was to be the future ingredient. It was also arranged that men should grease their own materials. But the mischief had been done, and the clever brains which had been plotting against the British, found a stimulant. In India no story is too wild for belief if connected with religion. There is no doubt that the first cartridges did contain material that would be entirely unclean, and there is no doubt that the fears of the sepoys were perfectly genuine.

At this time, too, when half India was agape and looked for a portent, the strange phenomenon of the *chappattis* occurred. The ordinary unleavened cakes of household use seemed to be passing round. A village watchman arrived at a village, distributed a cake, saying, "To the north, the south, the east and the west," with injunctions to make four more and increase the snowball. No one knew why they came. The watchmen only knew that someone had brought them. But it was known that in the past similar appearances had taken place in time of trouble.

The first signs of the approaching upheaval were displayed at the great military station of Barrackpore, 16m. from Calcutta, in Jan. 1857. The rumour regarding the cartridges which had originated at the adjacent Dumdum, had much inflamed the minds of the sepoys quartered there. The well-known sign of unrest, incendiary fires, broke out in the lines. Fortunately Gen. Hearsey was perhaps the best known and most experienced sepoy general in India, and active withal. Trouble was for the time laid by his judicious handling, but he warned the Government that he was sitting at Barrackpore on a mine ready for explosion. A month later the 19th Bengal Infantry at Berhampur refused to receive their percussion caps, on the ground that, to use the new cartridge meant defilement. The absence of any European troops necessitated a temporizing policy. The battalion was, however, ordered to march to Barrackpore for disbandment. Two days before its arrival, on March 29, a sepoy named Mangal Pandey,¹ drunk with *bhang* and religious enthusiasm, endeavoured to provoke an outbreak in his regiment, the 34th Native Infantry, shooting the adjutant who interfered, and cutting down the European sergeant-major of the battalion. The regimental guard failed to take action, but General Hearsey, who happened to be riding by, rode at the mutineer.

At this juncture, the gravest which had ever befallen the British in India, the commander-in-chief and his office, with all the military heads, were separated from the governor-general and the government by many hundreds of miles. Calcutta was the headquarters of government, and though on occasion the governors-general had summered at Simla during the wars with Afghanistan and the Sikhs, the offices and the ministers did not move. The commander-in-chief, finding the major portion of his army was in the north, had made Simla his headquarters. The absence of the commander-in-chief and the adjutant-general from the seat of government at this period made any concerted policy impossible.

The Outbreak at Meerut and Delhi.—By May 10 the situation developed in grim earnest, and what had fizzled at Berhampur and Barrackpore broke into flame at Meerut. Meerut was the largest station south of the Punjab, commanded by Major-Gen. Hewitt; and containing a considerable European garrison, viz., the Carabineers, the 60th Rifles and two troops of Bengal Horse Artillery, with the headquarters and principal depôt of the Bengal Artillery, commanded by Brigadier Archdale Wilson. Meerut was originally instituted to watch Delhi and the Mahratta frontier. The native troops were the 3rd Light Cavalry (a regular and non-silladar corps), and the 11th and 20th Bengal Native Infantry.

The officer commanding the cavalry, who had lately returned from leave, decided that the cartridge question must be faced, and ordered the sharpshooters of his regiment to receive the cartridge and practise the new loading drill. Eighty-five of the men refused, were tried by a native court-martial and sentenced to

¹From whose name, a common patronymic of Oudh Brahmans, the mutineers became known as "Pandies."

long terms of imprisonment for mutiny. At a general parade of the garrison the convicts were degraded and put in irons.

Just before dusk on the day succeeding the punishment parade, a Sunday, the native garrison broke out into open mutiny. The cavalry saddled and mounted and galloped to the gaol to release their comrades. The 11th Infantry shot the colonel of the 20th and fell on any of their own officers who came their way. As so often happens in large Indian cantonments, the European and Indian barracks lay some distance apart. At Meerut the two portions of the cantonment divided by a deep watercourse, were especially distinct. While the mutineers were murdering all Europeans they came across, aided by all the ruffians who always inhabit an Indian bazaar, the British troops, unaware of what was happening, were about to turn out for church parade which, at that season, was held in the evening, when the sound of firing broke on their ears. Fortunately the Rifles were not in church, and hurried to get under arms. The regimental sergeant-major ordered the men to exchange from white cotton to their invisible green clothing. When the British troops marched to the scene of the conflagration the mutineers were gone. A few rounds in the direction of the native lines cleared out any stragglers. The scenes of outrage did not continue. The cantonment was surrounded with woods and villages, and there were large numbers of women and children to be collected in a central place of refuge. The Carabineers themselves were hardly a regiment in being. Just out from Europe to replace a regiment sent to the Crimea, full of young soldiers, their horses were young walers,¹ as yet half trained. No one thought that the excited rabble of soldiers without their leaders was going to march straight to face the orderly brigade at Delhi, or that anyone could think of restoring the Moghul dynasty.

Whether, had the situation been grasped and correctly interpreted, Delhi could have been saved, can only be a matter of opinion. It has, however, been said that matters had gone too far for any local action to prevent the rebellion, and that Delhi, acting as a focus of the disease in the north, served a valuable purpose and contributed to its eventual suppression in a manner that could not have been foreseen. Early in the morning the mutinous cavalry reached Delhi, to be followed by parties of tramping redcoat sepoys. Attempts were made to prevent them entering the city and palace, but troops sent cheering from the cantonment three miles away, soon fraternized with the mutineers, and officers were shot down on all sides. The city and palace rabble hastened to massacre all Europeans and Christians. Those who took refuge in the palace were soon butchered. The whole of the civil lines which lay within the city wall became a shambles. Up on the ridge which lay between the cantonment and the city the brigadier with half his garrison stood to arms till dusk, the Europeans clustered at a small tower, the troops muttering and restless. Within the city walls, one of the most famous incidents in British history was taking place. Between the Kashmir Gate and the fortress-palace stood the great arsenal of upper India, left by some strange folly entirely in the hands of Indian troops, and within the city. Sir Charles Napier, when commander-in-chief, had protested, and the magazine itself had been moved to the end of the ridge in the cantonment. Within the arsenal there was an immense park of cannon, with a small "*expense*" magazine in which small-arms ammunition was made up. After defending the arsenal for as long as possible the resolute young artillery officers and warrant officers of the arsenal establishment, under Lt. Wilmoughby, blew up their magazine, causing great damage to their assailants, and sending a thrill of glory and defiance through the whole of India. This glorious act, however, had not the effect generally supposed, for unfortunately Sir Charles Napier's forethought in moving the main magazine had but resulted in its falling into the mutineers' hands. Without its contents (3,000 barrels of powder) the defence of Delhi by the mutineers would have been impossible. At sunset the remnant of the Europeans left Delhi for Meerut and Umballa as best they could. The ex-Moghul king was proclaimed by the soldiery and was put at the head of the rebellion.

A hundred and twenty miles north of Delhi lay the great mili-

¹Australian horses from New South Wales.

tary station of Umballa, the headquarters of a large military district commanded by Major-gen. Barnard of Crimean fame, which being in the newly occupied Punjab had many European troops. Of these, three battalions of European infantry were in the Simla hills for the summer, 60 to 80m. farther away. At Umballa itself were the 9th Lancers and two troops of European artillery with several native units. The commander-in-chief, General the Hon. George Anson, at once ordered all the Europeans in the Simla hills to march to the plains and the commander at Umballa was to get ready his force to march to Delhi. It was some days before the troops could be got down from the hills and supplies and transport collected. It must be remembered that there were practically no railways in India in 1857, and that the mutiny occurred in the height of the hot season. On May 17, six days after the outbreak at Delhi, the leading portion of the commander-in-chief's forces left Umballa for Kurnal, some 50m. down the Grand Trunk road, followed by a stream of detachments. The commander-in-chief proceeded to Kurnal on the 23rd and died there of cholera four days later.

With the rising at Delhi and the proclamation of the ex-king of Delhi to the throne of his fathers, the whole of the Bengal army, from Calcutta to Delhi, broke into revolt. At some stations the influence of individual officers held the regiments for a time, but with a few exceptions the whole of the Bengal Army and the contingents of the central Indian states caught the contagion. Scenes of tragedy and horror were enacted all over the Bengal presidency, especially along the great waterways of the Ganges and the Jumna. But from Calcutta to Meerut, a marching distance of 1,000 miles, the European garrisons were extremely small. At Lucknow, with one British battalion, Sir Henry Lawrence kept his troops in hand for weeks. At Cawnpore, Sir Hugh Wheeler, experienced but aged, tried to maintain a bold face with a few Europeans sent him by Sir Henry Lawrence. At Agra, one European battalion held the great fortress, and became a refuge for all the neighbouring provinces. As soon as the gravity of the situation was realized by Lord Canning, the governor-general, attempts were made to apply the only remedy, reinforcements of European troops. A battalion from Burma had been brought over when the trouble at Barrackpore had occurred. An expedition on the way to China was now summoned to help, and the European portion of the Persia expedition now returning to India was hurried to Calcutta. With the upper provinces isolated and telegraphs cut, with the commander-in-chief dead at Kurnal, it was necessary to organize a new chief command. General Sir Patrick Grant, the most famous of the Bengal sepoy officers of the day, was summoned from Madras, where he was provincial commander-in-chief. The pacification of the lower provinces first demanded the despatch of such small columns as could be organized to relieve the two places in the greatest danger—Sir Hugh Wheeler, at Cawnpore, Sir Henry Lawrence, at Lucknow.

To help the small stations was impossible. The restoration of order at the centre would automatically relieve them. Only in the Punjab, the most important of all the provinces, was the situation reassuring, and this for four reasons. First and foremost, the presence of a far larger number of European troops in the newly acquired provinces; secondly, the commanding character of the ruler, Sir John Lawrence; thirdly, the fact that the Punjabis had recently been handsomely beaten by the British and liked their new masters; fourthly, the pick of the young men of the Indian services were in civil and military employment in the north. Major-Gen. Reid, the senior general in the Punjab, though too old and unfit to cope with the situation, gallantly went off to Delhi to assume the provisional chief-ship when Anson died, to break down immediately from his exertions. But at Peshawur, the Brigadier, Sidney Cotton, was a tower of strength.

The eagerness, indeed, of Lawrence caused him to overlook the problem of moving Europeans in the Punjab summer and the want of carriage and equipment, nor did he at first realize the character of the revolt. Seeing that Delhi was the focus and should be recovered at all costs, and finding that even the combined Meerut and Umballa force could not take the city, he poured his British troops down, raising also innumerable levies to

replace the Bengal troops, who were disarmed at many stations. His boldness and that of Sidney Cotton, Neville Chamberlain and John Nicholson, charmed the wild Afghan and frontier tribes, who flocked to serve and share in the loot of Delhi. The Amir of Kabul, contrary to expectation, held by his alliance and refrained from attacking the British. Lawrence gambled and won. But it required every man he could raise before Delhi could be taken.

The Siege and Capture of Delhi.—By June the combined forces from Meerut, under General Barnard, the commander of the Umballa division, and Brigadier-General Wilson from Meerut, defeated the rebels in three engagements, and found themselves once again in the cantonment of Delhi.

The final reinforcements reached the ridge from the Punjab late in August—under Brigadier-General John Nicholson, who had hitherto passed rapidly up and down the Punjab disarming Bengal garrisons. With him came the last supplies of siege guns and ammunitions. The siege batteries then opened an intense fire on a short front of wall and bastion. At dawn on Sept. 14, three storming columns moved against the city, two entering up the breaches and the third blowing in the Kashmir Gate. The walls on the ridge side were soon in British hands, but with the price of Nicholson mortally wounded. Days of severe fighting were necessary to clear out the city and gain the fortress-palace. This finally done, the ex-king was captured at Humayun's Tomb outside Delhi, and the sons shot to avoid a rescue. The fittest of the troops then started south to relieve Agra.

The Coming of Reinforcements and the Relief of Lucknow.—The course of the Mutiny had four distinct phases:—(1) that of the outbreak, and the recapture of Delhi with the British garrison and Punjab troops which were chiefly stationed in the north of India; (2) the coming of reinforcements and the restoration of order along the course of the Ganges, with the relief of Lucknow; (3) the final capture of Lucknow in the spring of 1858 and the destruction of the second great centre of rebellion, and (4) the pacification of the country.

Sir Patrick Grant on his arrival had found a government in a military crisis, with no military headquarters. Not one single high official of the staff of the army nor any of its machinery was available. It was necessary to improvise and reconstruct an army machinery which would handle the large forces arriving for what was now clearly seen to be the re-conquest, not only of Bengal, but of most of Central India, to which the conflagration had now spread. Very soon came the news that government at home had appointed Sir Colin Campbell to succeed Anson, and Grant could only occupy himself with making a machine for Campbell to use. He did, however, push forward as soon as possible a column to relieve General Sir Hugh Wheeler at Cawnpore, and Sir Henry Lawrence at Lucknow, pushing up first Colonel Neil and his Madras Fusiliers, and then, as soon as he arrived, Gen. Havelock with more reinforcements.

The trunk road up country from Calcutta led straight across country to Benares on the Ganges, a distance of some 380m., of which the first 100 could be travelled on the recently opened commencement of the railway. Eighty miles farther lay the Moghul fortress of Allahabad at the junction of the Ganges and Jumna, and 120m. farther on lay the important military centre of Cawnpore, which had long watched the adjacent state of Oudh. At Cawnpore was Sir Hugh Wheeler's headquarters, with four native regiments and one European field battery. At Lucknow, 45m. distant, the headquarters of Sir Henry Lawrence and the administration of Oudh, was a European battalion and a large native force. Wheeler, greatly experienced in the sepoy army, realized that his troops were likely to mutiny, and that it must be a race against time. He was encumbered with a large number of women and children. It was essential to find a place of refuge, and choice lay between a fortified magazine a long way from the cantonment at the other side of the native city, or of fortifying some disused hospital buildings on the parade ground. Because of the difficulty of moving to the magazine, and of the importance of being easily reached by reinforcements expected early from the south, he decided on the latter. A company of the 32nd Foot from Lucknow came in to help garrison the

entrenchment, into which most of the Europeans moved on May 21. On May 31, about 150 men of the 84th Foot from Burma and a few Madras Fusiliers arrived. Believing that the crisis was passing, Sir Hugh sent a company of the 84th on to Lucknow. The total force of possible combatants in the entrenchment now was some 450 men, including civilian Europeans and Eurasians, with six guns, but there were 330 women and children. On June 4 and 5, the sepoys mutinied and marched for Delhi. But there lived, near Cawnpore, one Dundoo Punt, the Nana Sahib, adopted son of the ex-*Peishwa*,¹ who prevailed on the mutineers to return and attack the entrenchment, which they did on the 6th.

From the 6th to the 24th the garrison held out against heavy bombardment, and at last, worn out with heat and sickness, surrendered on promise of safe conduct by boat to Allahabad. Then followed the infamous massacre at the boats, and the collection of women and children to be murdered later. Neil and his Madras Fusiliers, pushing up from the railhead by bullock train and route march through great heat and heavy rain, first reached Benares in time to quell a mutiny there, and then threw himself into Allahabad, still garrisoned by a few artillery invalids and some Sikhs. Here he collected supplies, pushed parties up the road, and awaited Havelock, who was able to leave Allahabad on July 7, some of his troops moving by road and some by steamer. After several engagements with the mutineers Havelock heavily defeated their main force outside Cawnpore on the 16th, to find that all the women and children had been hacked to death in a small house known as the "Bibi-ghar" the night before. Their bodies, some still breathing, were thrown down an adjacent well, on which now stands an enduring monument. No act in the Mutiny raised so fierce a storm of anger.

At Lucknow, the headquarters of Sir Henry Lawrence and the administration of Oudh, the British still held out. Up till June 30, though there had been mutinies in Lucknow and in the neighbourhood, the garrison were not beleaguered. On the 30th Sir Henry, moving out to attack the mutineers at Chinhut, immediately incurred disaster, which not only severely crippled the force of Europeans, but compelled Lawrence to abandon outlying positions and concentrate in the group of houses known as the Residency. The garrison, 1,720 fighting men, of whom 712 were loyal sepoys, and 153 civilian volunteers, were now hotly beleaguered. Unfortunately Sir Henry Lawrence was fatally wounded by a shell on July 4, the command devolving on Brigadier Inglis. Gen. Havelock at Cawnpore was compelled to wait for reinforcements, and to collect carriage and supplies. It was not till late in September that he was able to advance to Lucknow. By the 25th he had reached the Residency, a reinforcement enabling the garrison to hold a less restricted area, but it had to remain for many weeks before the actual relief could come up.

In the meantime Sir Colin Campbell had arrived. By Nov. 3, he reached Cawnpore and was ready with 4,500 men to advance on Lucknow. That city had become the focus of rebellion of all who had not hurried to Delhi, and 60,000 armed men were collected round the devoted Lucknow garrison and its reinforcements. By Nov. 12, the force reached the Alumbagh, and by the 14th advanced on Lucknow. On the 16th the Sikandrabadh was stormed and Campbell joined hands with Outram and Havelock. The commander-in-chief had decided to withdraw the garrison and all its helpless folk at once, and to leave a strong force outside the city till he was prepared to attack the whole of the Lucknow rebel concentration. The success was marred by the death of the heroic Havelock, who was laid to his rest in the Alumbagh, in which Sir James Outram with 4,000 men was left to face the masses of the rebels till Sir Colin was ready.

The Campaign in Oudh and Central India.—Returning to Cawnpore with the rescued people, the chief was in time to save that important place from a sudden attack by the Gwalior rebels—and the second phase of the Mutiny, that of the coming of the reinforcements and the reopening of the Great Trunk road had now been accomplished. Cawnpore had been avenged and Lucknow relieved, while in the far north Delhi had fallen and

¹The deposed and pensioned chief of the Mahratta confederacy who lived in exile near Cawnpore.

the Delhi troops were marching south. It was not, however, till March, 1858, that Sir Colin had enough troops for his purpose, when Jang Bahadur, the prime minister of Nepal, had also arrived with 10,000 Gurkhas. The attack on the masses entrenched at Lucknow began on the 9th and partook of the nature of a siege, lasting till the 16th, when the city was in British hands and the whole rebel army routed. It was the brilliant campaign of Sir Hugh Rose in Central India which destroyed the last mutinous forces in being and clinched the suppression of the Mutiny.

The Central Indian Campaign.—Though the two great princes of Central India, Sindhia and Holkar, wisely and fortunately remained true to the British, troops belonging to both of them joined the mutineers. The Gwalior contingent of Sindhia's army mutinied in the middle of June, and on July 1 Holkar's troops revolted at Indore, and the resident, Henry Durand, was forced to leave the residency. The rani of Jhansi also rose in rebellion, to become known as "the best *man* upon the side of the enemy." The rising in this quarter received little attention until Jan. 1858, when Sir Hugh Rose was given the command of two brigades, to act in concert with Sir Colin Campbell, and he immediately began a campaign which for celerity and effectiveness has rarely been equalled in India. Advancing rapidly from Bombay, Sir Hugh Rose relieved Saugor on Feb. 3, after it had been invested by the rebels for upwards of seven months. On March 3, he forced the pass of Madanpur, and took the whole of the enemy's defences in rear, throwing them into panic. On the 21st he began the siege of Jhansi, the stronghold of the mutineers in Central India, with a garrison of 11,000 men. During the course of the siege Tantia Topi, the most capable native leader of the Mutiny, arrived with a fresh force of 20,000 men, and threatened the British camp; but Sir Hugh Rose, with a boldness which only success could justify, divided his force, and while still maintaining the siege of the fort, attacked Tantia Topi with only 1,500 men and completely routed him. This victory was won on April 1, and two days later Sir Hugh carried Jhansi by assault. On May 1 the battle of Kunch was fought and won in a temperature of 110° in the shade, many of the combatants on both sides being struck down by heat apoplexy. On May 22, the battle of Kalpi was won. In five months he had beaten the enemy in 13 general actions and sieges, and had captured some of the strongest forts in India. News now arrived that the rebel army under Tantia Topi and the rani of Jhansi had attacked Sindhia, whose troops had gone over to the rebels and delivered Gwalior into their hands. Sir Hugh marched against Gwalior at once, captured the Morar cantonments on June 16 and carried the whole of the Gwalior positions by assault on the 19th, thus restoring his state to Sindhia within 10 days of taking the field. This was the crowning stroke of the Central India campaign, and practically put an end to the Mutiny, though the work of stamping out its embers went on for many months, and was completed only with the capture and execution of Tantia Topi in April, 1859.

Nature of the Indian Mutiny.—The Indian Mutiny was in no sense universal. In the first place it practically occurred only in Bengal, Central India, the north-west provinces along the Ganges, Oudh and the Punjab, viz., those provinces garrisoned by the Bengal army and its off-shoots. The Madras line stood firm as did almost all that of Bombay. Seditious movements among the Mahrattas were kept in hand. Even in the affected districts the great mass of the people either stood neutral, waiting with the immemorial patience of the East to accept the yoke of the conqueror, or helped the British troops with food and service, in many cases also sheltering British fugitives to the best of their ability. The attempt to throw off the British yoke was confined to a few disaffected ex-rulers and their heirs, with their numerous clansmen and hangers-on, besides the badmashes and highwaymen who saw their way to profit by the removal of the British administration under which their peculiar talents found no outlet. The Bengal native army was their tool. But the fighting races of the Punjab saw no reason for casting in their lot with the mutineers, and the great majority of the independent princes who had nothing of which to complain, like Patiala and Jhind in the Punjab, preserved a loyal or at least an interested friendship.

The Sikhs showed their appreciation of Lawrence's admirable administration by keeping faith with their recent conquerors, and the Gurkhas of Nepal did yeoman service for their fathers' enemies.

The chief result of the Indian Mutiny was the end of the government of India by the East India company. It was felt that a system of administration which could permit such a catastrophe was no longer desirable. On Aug. 2, 1858, the queen signed the act which transferred the government of India to the crown. On Nov. 1, Lord Canning, then viceroy of India, published the noble proclamation in which the change was announced, and a full amnesty was offered to all the rebels who had not been leaders in the revolt or were not guilty of the murder of British subjects. The natives of India at large gratefully accepted the queen's proclamation as the charter of their lives and liberties, and a suitable opening to a new order.

INDIAN OCEAN, the ocean bounded north by India and Persia, south by the northern margin of the south polar continent (Antarctica), west by Arabia and Africa and east by Farther India, the Sunda islands and West and South Australia. From 35° South latitude there are no natural boundaries on the east and west, and artificial boundaries have therefore been laid down, consisting on the west of the meridian of Cape Agulhas, and on the east of the meridian of South Cape, Tasmania.

It attains its greatest breadth, more than 10,000 km. or 5,500 sea miles between the south points of Africa and Australia and becomes steadily narrower towards the north until it is divided by the Indian peninsula into two arms, the Arabian sea on the west and the Bay of Bengal on the east, the distance from Aden to Penang (Malay Peninsula) being 6,100 km. or 3,300 sea miles. Both branches meet the coast of Asia almost exactly on the Tropic of Cancer, but the Arabian sea communicates with the Red sea and the Persian gulf by the straits of Bab-el-Mandeb and Ormuz respectively. Both of these, again, extend in a north-westerly direction of 30° N. Within these boundaries the Indian ocean covers an area of 74,917,000 sq.km. It is thus the smallest of the 3 great oceanic basins comprising only 20.7% of the area of the oceans of the globe; 29.6% being covered by the Atlantic ocean and nearly half (i.e., 49.7%) by the Pacific. From a purely geographical standpoint the Indian ocean is not exclusively tropical in character, although, because the main shipping of the world only traverses the tropical portions as far as the southern coast of Africa and Australia, such is often assumed to be the case. The mean latitude may be fixed at 25° south; north of this, 34,280,00 sq.km. are in the tropical zone (i.e., 45.8%) whilst to the south 40,637,000 sq.km. lie outside the tropics. The two subsidiary basins, which are always included in its area, are very small; the Red sea has an area of 437,900 sq.km. (= about ½ of the area of Great Britain and Ireland); the Persian gulf has an area of 238,800 sq.km.

The Indian ocean receives few large rivers, the chief being the Zambesi, the Zhat el Arab, the Indus, the Ganges, the Brahmaputra and the Irawadi. Murray estimated the total land area draining to the Indian ocean at 130,080,000 sq.km. (= ½ the area

of Europe), almost the same as that draining to the Pacific. The Pacific, however, is more than twice as large as the Indian ocean. As, besides, the rivers mentioned, the South-western and North-western monsoons in the tropical regions on the eastern side of the Indian ocean bring heavy rains, and there is heavy rainfall also in the neighbourhood of the equatorial calms, the surface water in these regions contains very little salt, particularly in the Bay of Bengal into which flow the great rivers from the mainland.

Relief.—Large portions of the bed still remain unexplored, but a fair knowledge of its general form has been gained from the soundings of H.M.S. "Challenger," the German "Gazelle" expedition, and many British cable ships, and in 1898 information was greatly added to by the German "Valdivia" expedition and in 1905 by the British Percy Sladen Trust Expedition of H.M.S. "Sealark." A ridge for the most part less than 2,000 fathoms from the surface extends south-eastwards from the Cape. This ridge, on which the Crozet islands and Kerguelen are situated, is directly connected with the submarine plateau of the Antarctic in the neighbourhood of Kaiser Wilhelm Land (Gaussberg) at 90° E. From it the depth increases north-eastward to a deep hole south of South Australia, with depths of more than 2,750 fathoms, and northward to the angle between north-western Australia and the Sunda islands.

It has been ascertained that the ocean floor at this point has a peculiar formation, consisting of two long, narrow, deep-sea depressions lying parallel to the west coast of Sumatra and the south coast of Java. The depression nearest to the coast is 800 fathoms deep between Sumatra and the Mentawai islands, and from 1,500 to 2,000 fathoms deep south of Java; then comes a submarine ridge and beyond it a depression which is over 2,500 fathoms deep west of the Mentawai islands and 3,500 fathoms deep at a distance of 250 km. south of Java. All these submarine formations are strictly parallel to one another and are also parallel to the mountain ridges of the Sunda islands. In 1924 a Dutch submarine, by means of echo-soundings, measured depths of over 3,500 fathoms north-east of Christmas island. Along the shoal coasts of Further India, Africa and Madagascar, there are no such remarkable deep sea formations. In these western regions of the Indian ocean however, the Laccadive and Maldivé islands and the Chagos archipelago as far as Diego Garcia all rise from a single ridge; on another ridge lie the Seychelles with the Saya de Malha bank and the Nazareth bank as far as Mauritius. On this latter ridge the sea is, for the most part, not as much as 500 fathoms deep. Madagascar has also a submarine continuation to the south, and is moreover connected with Africa by a plateau less than 1,500 fathoms below the sea. The Persian gulf is very shallow, having a mean depth of only 13 fathoms; the Red sea is, in places, 1,000 fathoms deep.

Islands.—Like the Pacific, the Indian ocean contains more islands in the western than in the eastern half. Towards the centre, the Maldivé, Chagos, and Cocos groups are of characteristic coral formation, and coral reefs occur on most parts of the tropical coasts. There are many volcanic islands, as Mauritius, the Crozet islands and St. Paul's. The chief continental islands are Madagascar, Sokotra and Ceylon. Kerguelen, a desolate and uninhabited island near the centre of the Indian ocean in its southern part, is noteworthy as providing a base station for Antarctic exploration.

Deposits.—The bottom of the Bay of Bengal, of the northern part, of the Arabian sea, of the Red sea—with the exception of a narrow strip in the centre—and the Persian gulf, and the narrow coastal strips on the east and west sides of the ocean, are chiefly covered by blue and green muds. Off the African coasts there are large deposits of Glauconitic sands and muds at depths down to 1,000 fathoms, and on the banks where coral formation occurs there are large deposits of coral muds and sands. In the deeper parts the bed of the ocean is covered on the west and south by Globigerina ooze except for an elongated patch of red clay extending most of the distance from Sokotra to the Maldives. The red clay covers a nearly square area in the eastern part of the basin bounded on two sides by the Sunda islands and the west

coast of Australia, as well as two strips extending east and west from the southern margin of the square along the south of Australia, and nearly to Madagascar. In the northern portion of the square from Christmas island and across the Cocos islands to the southern tropics, the red clay is replaced over a large tract by Radiolarian ooze.

In the higher southern latitudes, that is, south of 50° South and almost to the ice boundaries, the bottom is covered with the siliceous deposit of the diatomous ooze; on the South Polar ridge however glacial marine sediments predominate, *i.e.*, continental deposits.

Temperature.—North of the southern tropics the temperature of the surface waters is at all times higher than 20° C and in the equatorial latitudes over 25°; in the eastern half it is generally above 27.5° C; in the Red sea and the Persian gulf the temperature often rises to above 30°. South of 40° the water quickly cools so that off Kerguelen (49° S.), even in summer the temperature has been found to be no more than 2–3° C. The isotherms move mainly from west to east, and their course is not diverted by currents to so great a degree as in the Atlantic. The distribution of deep sea temperatures is very similar to that of the Atlantic if it is borne in mind that the Indian ocean scarcely encroaches on the northern hemisphere. In the Indian ocean also the water to the depth of 50 m. to 800 m. or 1,000 m. is colder in the equatorial zone (0°–10° S.) than the water of higher latitudes, *e.g.*, than the water round the Madagascar-Mauritius coasts. At depths greater than 1,000 m. the temperature tends to become equalized, and at 2,000 m. it is almost always about 3° C and at 5,000 m. 1° C.

Salinity.—The saltiest surface water is found (a) in the Arabian sea and (b) along a belt extending from south-west Australia to south Africa, the highest salinity in this belt occurring at the Australian end. In both regions the salinity exceeds 36%. In the monsoon region west of Sumatra and throughout the Bay of Bengal, owing to rainfall and the inflow of rivers the salinity is diminished to 34% and at the mouth of the Hooghly to as little as 30%. In the northern portions of the Red sea and the Persian gulf on the other hand, the proportion of salinity is sometimes as high as 40%. South of New Amsterdam and São Paulo the salinity—as also the temperature—quickly diminishes, and south of Kerguelen as far as the South Pole there is a uniform “Polar water” containing 33.7% salinity. In the deep waters of the Indian ocean the saline distribution is for the most part the same as in the Atlantic ocean (*q.v.*) and therefore the circulation of the deep-sea layers of the Indian ocean is similar to that of the Atlantic. There are horizontal movements from north to south and from south to north in the different layers.

Meteorology.—In no oceanic division does the regular half-yearly alternation of all the factors in weather conditions and particularly the winds play such an important part as in the monsoon regions from 10° S. northward of the Indian ocean. From Oct.–Nov. to March–April north-east winds prevail in the north latitude and north-west winds in the south latitude; from May–June to Sept.–Oct. south-south-west winds prevail. In the Arabian sea between Sokotra and the Maldives these south-west monsoons are very violent and are dangerous even to modern steamship traffic. From the earliest times the voyages of the native sailing vessels between India and Africa have been regulated by these alternating winds. The south-west monsoon brings rain to the whole of India; the north-east monsoon is predominantly dry. Southwards from the latitude of the Seychelles—Chagos—Cocos islands, the south-east trade-wind prevails throughout the year, and south of 30° S. the west winds which are generally particularly strong between 40° and 55° lat., and of which in the 19th century the fast sailing ships bound for Australia and China took advantage. The tropical storms, especially of Mauritius, are much dreaded; they follow a parabolic course from east to west then southwards and back to the south-east, and occur in the summer season. In the Arabian sea and the Bay of Bengal these hurricanes are, fortunately, rare and occur only once or twice a year, in April–May and Oct.–Nov., that is to say, at the periods when the monsoons change. In the

Hooghly Delta off Calcutta the high waves which accompany the storms are dangerous and have caused the loss of thousands of lives.

Surface Currents.—The surface currents in nearly every case follow the winds and in the tropical regions, therefore, are regulated by the monsoons. The currents running north-east and east caused by the powerful south-west monsoon during the northern summer in these regions—as in the Gulf stream off Florida—ships may be sent from 60 to 100 sea miles, or 100 to 150 km. out of their course in 24 hours. During the north-east monsoons the water of the Indian ocean in north latitude flows west and south-west, and a contrary current between the equator and 10° S. flows eastward towards western Sumatra. In the region of the south-east tradewind the so-called South equatorial current flows on continuously westwards, and divides into two streams at Cape Amber (Madagascar). The northern half flows up to the coast of Africa and then turns south through the Mozambique channel, to form at a later stage the famous Agulhas current of the South African coast; the other half flows along the east coast of Madagascar as the Mascarene current and gradually turns to the south-east. The Agulhas current also often runs very swiftly westward off the ridge of the Agulhas bank; as the wind drives the waves in an easterly direction, this causes a highly unpleasant motion of the sea.

On clearing the land south of the Cape the waters of the Agulhas current meet those of the west wind drift of the Southern ocean, and mingle with them in such a manner as to produce, by interdigitation, alternate strips of warm and cold water, which are met with at great distances south-west and south of the Cape. Between South Africa and Australia the waters form a part of the great west wind drift. The waters of this drift are, in general, of very low temperature, but it is remarkable that the interdigitation just mentioned continues far to the eastward, at least as far as Kerguelen. The west wind drift sends a stream northwards along the west coast of Australia in a north-westerly direction, but this is not cold, like the corresponding Benguela current of the south Atlantic; in Western Australia, therefore, there is almost an entire absence of the cold coastal waters and the fogs, so characteristic of the coast of south-west Africa.

In the high south latitudes of the Indian ocean a wide stream of cold water flows from the south polar continent towards the north-west, north and north-east; this stream carries pack ice and frequently large numbers of icebergs as far as the Prince Edward islands, the Crozet islands and Kerguelen, and sometimes even up to the sea-routes between South Africa and South Australia.

INDIANOLA, a city of Iowa, U.S.A., 18m. S. by E. of Des Moines; the county seat of Warren county. It is on Federal highway 65, and is served by the Burlington and the Rock Island railways. The population in 1925 (State census) was 3,581. It is the seat of Simpson college, a Methodist Episcopal institution established in 1867. Indianola was laid out and made the county seat in 1849. It was incorporated in 1864 and chartered as a city in 1884.

INDIAN PAINT-BRUSH: see PAINT-BRUSH.

INDIAN PHILOSOPHY. It is not possible to determine exactly the dates of the Indian systems of philosophy. The following, however, may be accepted as the broad divisions of the philosophic development:—I. The Vedic period (*c.* 1500–600 B.C.); II. The Epic period (600 B.C. to A.D. 200); III. The period of the six systems (A.D. 200).

I. THE VEDIC PERIOD

The Vedic literature comprises (1) the four Vedas, which consist of hymns, prayers and spells addressed to the gods; (2) the Brāhmaṇas or ritual treatises; (3) the Āraṇyakas, or the forest treatises, which constitute the concluding portions of the Brāhmaṇas; and (4) the Upaniṣhads, which form the basis of much of the later Indian philosophy. The religion of Nature of the hymns, the religion of law of the Brāhmaṇas and the religion of spirit of the Upaniṣhads correspond in a very close way to the three great divisions in the Hegelian conception of the growth of religion.

The Rg Veda.—The Rg Veda represents the thought of successive generations of thinkers, and so contains within it different strata of thought. We see in it the development of religious ideas from the animistic to the absolutistic stages. "Where is the sun by night?" "Where go the stars by day?" "Why does the sun not fall down?" "Of the two, night and day, which is the earlier, which the later?" "Whence comes the wind, and whither goes it?" These are some of the questions which harassed the mind of the early Aryan. His first efforts to answer them resulted in naturalistic polytheism. There is a deity which makes the strong wind to blow, the lightning to flash and the thunder to roll. While some of the chief Vedic deities like Indra and Varuṇa are completely emancipated from connection with the phenomena of Nature which originally suggested them, others like Sūrya (Sun) and Agni (Fire) are conceived on the lines of the actual phenomena whose names they bear. In some later hymns we have abstract deities which show no traces of connection with natural phenomena, as Prajāpati ("lord of creatures"), or personifications of pure abstractions, as S'raddhā (Faith), Manyu (Wrath). The conception of Varuṇa, the lord of physical and moral order, reaches a high level and is majestic enough both in its cosmical and ethical aspects. Varuṇa is the lord of *ṛta*: *ṛta* refers to the physical order in the universe, the order of the sacrifice and the moral law of the world. On account of *ṛta*, the sun pursues his daily, and the moon her nightly, journey across the sky and the silent procession of the seasons moves regularly in light and shadow, in cloud and sunshine across the earth. The doctrine of karma is a reformulation of this principle of *ṛta*.

When mythical conceptions from beyond the limits of the Aryan world belonging to a different order of thought entered into the Vedic pantheon sceptical tendencies developed. There were men who were harassed by the doubts "who is Indra? whoever saw him?" "To what god shall we offer our oblation?" (X. 121.) Some men were devoid of faith. An undercurrent of satire may be noticed in some of the hymns (RV IX. 112; X. 119; VII. 103).

Monotheism.—The crowding of gods and goddesses proved a weariness to the intellect. Attempts were made to identify one god with another or throw all the gods together. The close connection of the elements in Nature helped the growth of syncretism. An orderly system of Nature signified by the conception of *ṛta* has no room for miraculous interferences in which alone superstition and confused thought find the signs of polytheism. Besides, religious consciousness is naturally inclined to believe that the supreme is one. What is called henotheism or the worshipping of each divinity in turn as if it were the greatest and even the only god is the expression of the logic of religion. When the same functions of establishing the earth and sustaining the air and the sky are assigned to the different deities we tend to drop the peculiarities and make a god of the common functions. This becomes easy when the several gods are not clear-cut individuals but cloudy and confused concepts. The supreme is identified with Prajāpati (X. 85. 43, 184. 4, 189. 4), sometimes with Hiranyagarbha (X. 121), sometimes with Bṛhaspati (X. 72).

Monism.—Those dissatisfied with monotheism argue that there is one impersonal reality of which Agni, Indra, Varuṇa are the names or forms. "The real is one, the learned call it by various names." This one is the soul of the world, the reason immanent in the universe (X. 129. 2). "Priests and poets with words make into many the hidden reality which is but one." (X. 114.) Our minds seem to be satisfied with inadequate images of this reality,

"the idols which we here adore."

Cosmology.—At the pluralistic stage the deities are looked upon as the authors of the universe who create it by a process of manufacture or organic development or through the power of the sacrifice (X. 123. 1). When we rise to the monotheistic level the one god creates the world with the help of pre-existent matter (X. 121). Sometimes the dualism of the creator and the pre-existent matter is overcome and God is said to create the world out of his own nature. In the *Puruṣasūkta* (X. 90) the world is produced by the gods from the sacrifice of a primeval *puruṣa* (person). This person is all that has been, is, and shall be. But the most advanced theory of creation is suggested in the *Nūsadiya* hymn (X. 129). It starts with the assertion that in the beginning there was neither being nor non-being, neither air nor sky, neither death nor immortality, neither night nor day. There was nothing else save the one which breathed breathless, of its own power. This is the poet's way of describing the primal unconditional ground of all being, which is beyond our categories. The third verse states that through the power of *tapas* (austerity), the first antithesis of being and non-being, the active energy and the passive matter is produced. Through desire (*kāma*), which is the germ of mind (*manasoretaḥ*), the rest of the development takes place. Desire, which is the sign of self-consciousness, is the bond binding the existent and the non-existent. We cannot say why the original being develops into an active creator and the passive chaos. The hymn concludes with an expression of doubt. Creation is a mystery. *Ko veda?* ("who knows?")

Future Life.—A healthy joy in life dominates the Rg Veda. The worshipper asks not for immortality or heaven but a long life for a full 100 years. There is belief in future life, a heaven for the good and a hell for the wicked. Reward follows righteousness and punishment misconduct.

THE UPANIṢHADS

The Upaniṣhads form the concluding portions of the Veda and are therefore called Vedānta or the end of the Veda. Their aim is not so much to reach philosophical truth as to bring peace and freedom to the anxious human spirit. They represent free and bold attempts to find out the truth without any thought of a system. Notwithstanding the variety of authorship and the period of time covered by them, we discern in them a unity of purpose and a vivid sense of spiritual reality. They are distinguished from the Vedic hymns and the Brāhmaṇas by their increased emphasis on monistic suggestions and subjective analysis as well as their indifference to Vedic authority and ceremonial piety.

Metaphysics.—The *Taittirīya Upaniṣhad* (III.) gives us an account of the gradual evolution of our ideas regarding the ultimate basis of things. The seeker tries to find out the one comprehensive principle from which "all things are born, by which they are sustained and into which they return at death." His first answer that matter (*amam*) is the basic principle is discarded in view of its inadequacy to vital phenomena. The second answer of life (*prāṇa*) is found unsatisfactory when sentient entities are considered. The third suggestion of mind (*manas*) is incapable of accounting for logical phenomena and the fourth formula of logical intelligence (*viññāna*) cannot be regarded as the highest reality, since there are aspects of being which cannot be reduced to intellectual terms. Thought as ordinarily understood deals with objects viewed as beyond or other than the process of thinking. Reality can be reached in the state of highest immediacy which transcends thought and its distinctions, which is *ānanda* or bliss. *Ānanda* is Brahman.

Subjective Analysis. Ātman.—The *Chāndogya Upaniṣhad* (VIII. 3. 12) institutes an enquiry into the nature of the self. The body which is born, grows up, decays and dies cannot be the true self which persists throughout the changes of birth and death. The dreaming self, subject as it is to the accidents of experience, must not be confused with the true self. The self is not the unity of the evergrowing and changing mental experiences. The self in dreamless sleep cannot satisfy our need, since it is empty of all content and is a bare abstraction. The true self is said to be the universal consciousness existing both in itself

and for itself. The *Māṇḍūkya Upaniṣhad* observes that the three states of the soul—waking, dreaming and sleeping—are included in a fourth (*turiya*) which is intuitional consciousness, where there is no knowledge of objects, internal or external. It is the unchanged and persistent identity which continues in the midst of all change. It is the *Ātman*.

Brahman and *Ātman* are one. The inmost being of universal nature is the same as our innermost self. *Tat tvam asi*: "that art thou." The nature of this ultimate reality cannot be defined. It can be grasped, however, through intuition. This intuition is not objective like perceptual experience or communicable to others like inferential knowledge. We cannot give a formal exposition of it. To any suggested definition of reality we can only say, "not this," "not this" (*neti, neti*. Brh. IV. 2. 4). Contradictory accounts are given to show that negative descriptions do not mean negation of all being but only the poverty of intellect.

We cannot, however, remain long at this high level. We insist on framing intellectual pictures of the absolute. When the *Ātman* is identified with the self-conscious individual, Brahman is described as a personal being (*Īśvara*). When the *Ātman* is identified with the mental and the vital self, Brahman becomes the cosmic soul (*Hiraṇyagarbha*). When the *Ātman* is taken for the body, Brahman is taken for the cosmos (*Virāt*). Brahman is the sole and the whole explanation of the world, its material and efficient cause. The metaphors of the spinning of the web by the spider, the bearing of the child by the mother, the production of notes from musical instruments point to the oneness of Brahman and the world. There is, however, no logical deduction of the world of multiplicity from the ultimate cause. At the theistic level the world is regarded as the self-limitation of the supreme. The power of self-expression possessed by the personal *Īśvara* (God) is sometimes called *Māyā*.

The Doctrine of *Māyā*.—There is hardly any suggestion in the Upaniṣhads that the entire universe of change is a baseless fabric of fancy. The dominant note of pantheism goes against this view. The assertion of the sole reality of Brahman denies duality and traces all change to Brahman but does not suggest that change is illusion. The frequent emphasis on the oneness of the world and Brahman need not be repudiated as a mere concession to common-sense ideas. The texts which declare that the variegated universe is due to the development of name and form from out of the one Brahman warn us against getting lost in the world of multiplicity. The passing semblance of life is in no wise its immortal truth. The theory of the world-illusion is inconsistent with the conception of degrees of reality, or, to be more accurate, unreality which is found in the *Aitareya Āraṇyaka* (II. 3. 2 *et seq.*). When Yājñavalkya contends that duality is necessary for empirical consciousness and suggests that the world of duality is not real by the use of the particle '*iva*' (Brh. Up. II. 4. 14; IV. 3. 31), he refers to the non-ultimate character of the world of duality.

Ethics.—*Mokṣa* is release from the bondage to the sensuous and the individual. The morality of the Upaniṣhads is, in a sense, individualistic as it emphasises self-realization. The term "individualistic," however, ceases to have any exclusive meaning. To realize oneself is to identify oneself with a good that is not private to any one. Insistence on the knowledge of God (*jñāna*) is tempered by the recognition of the need for moral life.

When the moral striving ends in religious realization the individual is said to be freed from all moral laws. This does not mean that the free can do what they choose with perfect impunity. Laws and regulations are necessary for those who do not naturally conform to the dictates of morality. For those who have risen above the selfish ego and who have died to sin morality is the very condition of their being.

Those who have not reached the highest perfection will have other chances for striving. *Samsāra* offers a succession of spiritual opportunities. The hypothesis of rebirth is formulated in this period (Chān. V. 3. 10; Brh. VI. 2.), though there are still compromises with the Vedic views. Good and evil actions experience a twofold retribution, once in the other world and again by a renewed life on earth.

Moral striving is governed by the law of *karma*. Our life carries within it a record that time cannot blur or death erase. The soul that sinneth, it shall die. Though we cannot efface the results of our acts on the outer universe, its effects on us can be wiped away by strenuous exertion. *Karma* emphasizes individual responsibility. It is more favourable to self-culture and meditation than to prayer and petition.

In every sphere the Upaniṣhads indulged in inconsistent compromises with the Vedic views. The chaos of the Brahmanical religion reached its climax in the post-Upaniṣhad or pre-Buddhist period when truth hardened into tradition and morality stiffened into routine. The need for reconstruction was felt by the thinking minds.

II. THE EPIC PERIOD

The systems of materialism, Jainism and Buddhism, belong to the Epic period, which is the age of reconstruction.

Materialism.—Materialism is called *Lokāyata* (directed to the world), as it holds that only this world (*loka*) is real. According to it, perception is the only source of knowledge. Inference which assumes universal relations, testimony and analogy are all defective. Matter is the only reality, of which the elements are earth, water, fire and air. Consciousness is a function of matter. There are different opinions about the nature of the soul. It is identified with the gross body or the senses or breath or thought. There is no future life. As the soul is an attribute of the body, it comes into being when the body is formed by the combination of the elements even as the power of intoxication arises from the mixture of certain ingredients. When the body is destroyed the soul disappears. The world is born of itself. God is a myth which we accept—thanks to our ignorance and incapacity. Pleasure and pain are the central facts of life. Virtue and vice are conventions.

Jainism.—Vardhamāna (c. 599–527 B.C.), the founder of Jainism, is a slightly older contemporary of Buddha. He is said to have systematized the faith held by a succession of 23 other sages, of whom the chief was Pārśvanātha (c. 776 B.C.).

Theory of Knowledge.—Jainism assumes that truth is relative to our standpoints. The Jains are fond of quoting the old story of the six blind men who each laid hands on a different part of the elephant and tried to describe the whole animal. The man who caught the ear thought that the creature resembled a winnowing fan; the holder of the leg imagined that he was clinging to a big round pillar, and so on. It was he who saw the whole that perceived that each had only a portion of the truth. The doctrine of *nayas* brings out this relativity of thought. The most important application of this doctrine is the theory of *Syādvāda* or *Saptabhāṅgī*. Every proposition gives us only a perhaps, a may be, or a *syāt*. We cannot affirm or deny anything absolutely of any object, owing to the endless complexity of things. Being is not of a persistent unalterable nature. Every statement of a thing is necessarily one-sided and incomplete. If we take it as true and complete we make a mistake. There are seven different ways of speaking of a thing or its attributes according to the point of view. All things, *i.e.*, substances (*dravya*) are divided into lifeless (*ajīva*) and living (*jīva*). The former are again divided into (1), space (*ākāśa*), (2) and (3), two subtle substances called *dharma* and *adharma* and (4), matter (*puṅgava*). Space, *dharma* and *adharma* are the necessary conditions for the subsistence of all other things, *viz.*, souls and matter. Space affords them room to exist; *dharma* makes it possible for them to move or be moved, and *adharma* to rest. Time is recognized by some as a quasi-substance beside those mentioned. Matter is eternal though it may assume forms as earth, air and so on. It exists in the two forms of atoms (*anu*) and aggregates (*skandha*). The changes of the physical universe are traced to atomic aggregation and disintegration. The atoms are not constant in their nature but are subject to change or development (*pariṇāma*), which consists in their assuming new qualities. There are not different kinds of atoms answering to the different elements of earth, water, fire and air. Homogeneous atoms produce different elements by varying combinations. While things which we perceive are made of gross matter, there is matter beyond the reach of our senses in subtle form which is transformed into the different degrees of *karma*.

This kind of matter fills all space. The soul by its commerce with the outer world becomes literally penetrated with the particles of this subtle matter. *Karma* works in such a way that every change leaves a mark which is retained and built up into the organism to serve as the foundation for future action.

The characteristic essence of the soul is consciousness (*ceṭana*), which is never destroyed, however much it may be obscured by external causes. The souls are said to possess size, which varies with the nature of the bodies with which they happen to be connected. Subtle matter coming into contact with the soul causes its embodiment. Being then transformed into eight kinds of *karma* and forming, as it were, a subtle body, it clings to the soul in all its migrations. The individual soul (*jīva*) is a composite of consciousness and matter or body. Jainism believes that there are souls even in inorganic objects, though they lie dormant in them.

Jainism does not believe in God, though the souls can reach a divine status. The souls and the world are self-existent and eternal. The chief means to the end of *nirvāṇa* is the performance of austerities. By it we destroy the old *karma* and prevent the formation of the new. Right faith, right knowledge and right conduct are recommended. The peculiarity of the Jaina ethics is its insistence on avoidance of taking life of any kind.

Early Buddhism also falls within the Epic period, but is dealt with in the articles **BUDDHA** and **BUDDHISM**.

III. THE SIX SYSTEMS

The revolt of Buddhism and Jainism helped to bring about a critical point of view and led to the great movement of philosophy which produced the six systems of thought, where criticism and analysis take the place of poetry and religion. The different systems are not antagonistic but are complementary. They are regarded as an evolutionary chain, a single and gradually advancing series rather than as destructive of one another. Each of them is a metaphysics and a religion, an explanation of the world and a method of salvation.

THE NYĀYA

Logic as epistemology may be called a critical reflection on metaphysics. The *Vaiśeṣika*, which deals with the analysis of nature, is earlier than the *Nyāya*, which discusses the problem of knowledge; yet we start with the latter, as it gives the main logical principles assumed by the *Vaiśeṣika* as well.

Assuming that the account of the world which our minds afford us is, in the main, a trustworthy one, the *Nyāya* analyses the different ways in which our knowledge is acquired. They are said to be intuition (*pratyakṣa*), inference (*anumāna*), comparison (*upamāna*), and verbal testimony (*śabda*). Though *pratyakṣa* originally meant sense-perception, it soon came to cover all immediate apprehension whether through the aid of the senses or otherwise. It is knowledge whose instrumental cause is not knowledge (*jñānākaraṇakam jñānam*). In inference, comparison, etc., we require a knowledge of premises or of similarity, but such knowledge is not an antecedent condition of intuition. The word is used for the result or the apprehension of the truth as well as the process or the operation which leads to the result.

Sense-perception follows on the modification of the self produced by the contact of the senses with their objects. Two kinds of perception are distinguished, determinate (*savikalpaka*) and indeterminate (*nirvikalpaka*), which correspond roughly to knowledge about and acquaintance with an object.

Inference.—Inference operates "neither with regard to things unknown nor with regard to those known definitely for certain; it functions only with regard to things that are doubtful" (N. B. I. I. i.). It derives a conclusion from the ascertained fact of the subject possessing a property which is constantly accompanied by another. We ascertain that the hill is on fire from the fact that the hill has smoke and smoke is universally accompanied by fire. Inferential reasoning is stated in the form of a syllogism of which the five members are 1, proposition (*pratijñā*): the hill is on fire; 2, reason (*hetu*): because it smokes; 3, example (*udāharana*): whatever shows smoke shows fire, e.g., a kitchen; 4, application (*upanaya*): so is this hill, and 5, conclusion (*niṣaṃana*): therefore, the hill is on fire. The first member states the thesis to be

established. It is only a suggestion. It contains a subject or what is observed, which is generally an individual or a class, and a predicate which is to be proved. The subject is the minor term (*pakṣa*, *dharmīn*) and the predicate the major (*sādhya*, *dharmā*). The second member of the syllogism states the presence in the minor of the middle term called ground (*hetu*). The third takes us to the basis of inference, the major premise. Though Gautama and Vātsyāyana may not have regarded the example as the illustration of a general rule, later *Nyāya* looks upon it as the statement of an invariable concomitance between the mark and the character inferred (*vyāptipratipādikam vākyam*). The conclusion restates the proposition as grounded. Nāgārjuna is given the credit for dispensing with the last two members of the syllogism as superfluous.

Induction.—Universal propositions are reached through enumeration, intuition and indirect proof. Uninterrupted agreement (*nīyata sādhacarya*) reinforced by absence of exceptions (*avinābhāvārūpasambandha*) leads to unconditional concomitances. Nature does not always supply us with positive and negative instances of the necessary type. In such cases indirect proof (*tarka*) may be used. By pointing out the absurdities in which we are landed, if we deny a suggested hypothesis, we indirectly prove its validity. Even when we observe all possible cases and strengthen our conclusion by indirect proof we cannot reach absolute certainty. Experience of sensible particulars, however thorough and exhaustive, cannot give rise to universal relations. Gaṅgeśa recognizes the nonsensuous (*alaukika*) activity involved in the apprehension of universals (*sāmānyalakṣaṇa*).

Causation.—A cause is that which invariably precedes the effect. It is not merely accessory to but is necessary for the production of the effect. Two things cannot be causally related unless there is the positive-negative (*anvayavyatireki*) relation between them, such that the presence of the cause means the presence of the effect and vice versa. Three different kinds of causes are distinguished, material (*upādāna*), non-material or formal (*asamavāyi*) and efficient (*nimitta*). The appearance of plurality of causes is traced to defective analysis. When the effect is understood in its uniqueness (*kāryaviśeṣa*) it will be seen to have only one cause.

Comparison.—By means of comparison (*upamāna*), we gain the knowledge of a thing from its similarity to another thing previously well known. Hearing that *gavaya* (wild ox) is like a cow, we infer that the animal which we find to be like the cow is the *gavaya*. This argument involves knowledge of the object to be known and perception of similarity. Comparison relates to the problem of identification.

The problem of *śabda* or verbal knowledge is mainly of theological interest. Certain questions of logical value are incidentally discussed. Regarding the import of words, the *Nyāya* holds that a word denotes an individual (*vyakti*), or a form (*ākṛti*) or a genus (*jāti*) or all these. It depends on our particular interest at the moment.

The validity of knowledge is not self-established but is proved by something else (*parataḥ pramāṇa*). If every cognition were self-evident there would be no possibility of doubt. We discover the truth of our ideas by the test of action.

Metaphysics.—The individual self is a real substantive being possessing the qualities of knowledge, feeling and desire and aversion. It is different from the body, the senses and the understanding. It is all-pervading though it does not cognize many things simultaneously on account of the atomic nature of *manas* or the inner sense. It is unique in each individual, and we have an infinite number of souls. The soul is an unconscious principle capable of being qualified by consciousness.

THE VAIŚEṢIKA

The system takes its name from *viśeṣa* or particularity. It is in the particulars of the world, pre-eminently in the particular imperceptible souls and atoms, that true individuality is to be found.

Categories.—The *Vaiśeṣika* adopts a sixfold classification of *padārthas* (objects which can be thought and named) into sub-

stance (*dravya*), quality (*guṇa*), movement (*karma*), generality (*sāmānya*), particularity (*viśeṣa*) and inherence (*samavāya*), to which later thinkers add a seventh, non-existence (*abhāva*). That something is, is the first principle; but nothing can be without possessing certain qualities. Some of the qualities reside in a plurality of objects, while others are confined to individuals. The former are general qualities (*sāmānya*), while the latter are distinguished into permanent (*guṇa*) and transitory (*karma*). Inherence is a special kind of relation distinct from occasional or separable conjunction. When the scheme became logical in scope non-existence was included. Later Nyāya develops this idea with great subtlety. The first three categories possess a real objective existence, while the other three are products of intellectual discrimination.

Atomic Theory.—The atomic theory is developed in connection with the substances of earth, water, light and air. The things that we experience are made up of parts. They are therefore non-eternal. Non-eternal has no meaning apart from eternal. The component particles are eternal. The atom marks the limit of division. If it were endlessly divisible, then material things would be products of an equally endless number of constituent parts, and differences in the dimensions of things could not be accounted for. Though the atoms have no extension, their heterogeneous nature is the cause of the extension and visibility of the combinations of atoms. Though Kaṇāda is not clear about where the visibility of the combinations begins, his later followers suggest that an aggregate of three atoms (*tryaṇuka*), others of three double atoms, produces extension, and it is visible in the shape of the dust mote (*trasareṇu*) dancing in the sunlight. Answering to the four kinds of material objects—earth, water, light and air, we have four kinds of atoms producing the four senses of touch, taste, sight and smell. This is why each special sense reveals a single quality, however excited. Though the qualities of earthly things, as colour, taste, smell and tangibility, vanish on the destruction of the thing itself, they are always found in their respective atoms, though in earth and atoms of earth new qualities are produced by heat (*pākaja*). Water, light and air do not suffer a similar change. There can never come a time when there will be an utter annihilation of things. The atoms will abide for ever.

THE SĀMĀNYA

The *Sāmkhya* is a reaction against the idealistic monism of the Upanishads. It believes in a real matter and an infinite plurality of individual souls which are not emanations of a single world-soul.

The *Sāmkhya* adopts the view that the cause and the effect are the undeveloped and the developed states of one and the same substance. Development is the coming to light of what is latent or hidden even as destruction is disappearance into the original cause. There is no such thing as utter annihilation. Applying this principle, the ultimate basis of the empirical universe is said to be *prakṛti* (nature). The world is the transformation of *prakṛti* (nature), which cannot be equated with any one of the stages of its evolution.

Prakṛti (nature) is a string of three strands or *guṇas*, *sattva* or potential consciousness, *rajas* or activity and *tamas* or restraint. They are called *guṇas* (qualities), as they are factors in the substance of *prakṛti* (nature). They represent different stages in the evolution of any particular phenomenon. *Sattva* signifies the essence or the form which is to be realized, *tamas* the obstacles to its realization, and *rajas* the force by which the obstacles are overcome. The *guṇas* are always changing, but when they are held together in a state of equilibrium (*sāmyāvastha*) there is no action. The tendencies to manifestation and activity are held in check by that of non-manifestation and non-activity. When the tension is relieved development results. *Prakṛti* (nature) evolves under the influence of *puruṣa* (subject) into the apparatus of thought as well as the objects of thought.

Theory of Evolution.—The first product of the evolution of *prakṛti* (nature) is *mahat*, "the great" or *buddhi* (intelligence). Self-sense (*ahamkāra*), or the principle of individuation, arises next. From this, in its *sattva* aspect, arise the *manas* (internal organ), the five organs of perception and the five of action; from the same in the *tamas* aspect the five fine elements (*tanmātras*)

arise. The *rajas* element helps both. From the five fine elements, by a preponderance of *tamas*, the five gross elements are produced. The account is probably suggested by the subject's experience and transferred to a cosmic plane. In the state of dreamless sleep the self is present, though it does not apprehend the world. So, in the case of world dissolution, the selves are not distinguished and *prakṛti* (nature) is unperceived. When one wakes from sleep there is, first, the rise of consciousness, followed immediately by the sense of selfhood and the restlessness of desire. The senses begin to function until the world is perceived. This order is followed in the *Sāmkhya* theory of evolution.

Plurality of Souls.—*Puruṣa* is the intelligent self, for whose experience *prakṛti* (nature) evolves. It is a mere witness, a solitary indifferent spectator. It is pure consciousness while *prakṛti* (nature) is unconscious. It is inactive, unalterably constant, and devoid of the *guṇas* while *prakṛti* is active, alterably constant and consists of them. *Prakṛti* and its products depend for their manifestation on the light of *puruṣa* (self), which does not depend on anything else for illuminating objects. The *Sāmkhya* believes in a plurality of selves. If the self were one all should become free when one attained freedom, which is not the case. Freedom is not coalescence with the absolute spirit but isolation from *prakṛti*.

The empirical individual is not the pure self but the self distinguished by the conjunction of the senses, etc., and limited by the body. While the pure self remains beyond the intellect the reflection of the self in it appears as the ego. Activity belongs to the intellect, and on account of its union with *puruṣa* (self) the indifferent self appears as an actor. Though not an agent, the self appears as an agent through confusion with the agency of nature, even as the latter through proximity to the self appears to be conscious. Every ego possesses within the gross material body, which suffers dissolution, a subtle body formed of the psychical apparatus including the senses. This subtle body is the basis of rebirth as well as the principle of identity in the various existences.

The evolution of nature is adapted to the ends of the self. The spiritual centres are, however, incapable of exerting any direct influence on nature, though they are said to excite it to activity. The union of self and nature is compared to a lame man of good vision mounted on the shoulders of a blind man of sure foot.

The real self has relations with a real world on account of a fancied relation between the two. When the self recognizes its distinction from the ever evolving and dissolving world of nature the latter ceases to operate towards it. The efficient cause of the development of nature is not the mere presence of the selves but their non-discrimination. Freedom is the result of discrimination. No cause is assigned for the original entanglement of the free spirits in the bonds of ignorance.

THE YOGA

The Yoga differs from the *Sāmkhya* in its insistence on mental discipline and acceptance of theism, though its connection with belief in God is somewhat loose. God does not create, reward or punish. Union with God is not the goal of Yoga endeavour. God is only a particular soul not essentially different from other souls co-eternal with him. He stands in an eternal connection with the most refined constituent of matter and is endowed with supreme power, wisdom and goodness.

Our bondage is due to non-discrimination. The true light of the spirit will shine if the obscuring mental activities are suppressed. The method of Yoga consists in the suppression of all mental activities, conscious as well as unconscious. The eightfold path is a means of it. The first two, *yama* (abstention) and *niyama* (observance), refer to the ethical preparation. The next two *āsana* (posture), *prāṇāyāma* (regulation of breath) insist on the discipline of the body so as to make it flexible. We can control involuntary muscles as well by the breathing exercises. The next step of *pratyāhāra* or the withdrawal of the senses from their natural outward functioning answers to what modern psychology calls introversion. While these five are only accessories, *dhyāna* (fixed attention), *dhāraṇa* (contemplation), and *samādhi* (concentration) are integral elements of Yoga. Through concentration we get into direct touch with the reality of the things and obtain

intuitional knowledge. The process of concentration is to be continued until the mind is dissolved and self illumination results. *Samādhi* is the perfect life of spirit.

THE PŪRVA MĪMĀMSĀ

The Pūrva Mīmāṃsā has for its special object the ascertainment of duty (*dharma*). It is not a philosophical system, though it refers to philosophical topics incidentally. It believes in the reality of the world and the individual souls. As it deals with ritual specially, it points out how every act produces its effect sometime or other through the principle of *apūrva* or the link between the act and the result. While the earlier writings do not admit the existence of God, the later ones do.

A chief writer of this school, Kumārila argues for the theory of self-evidence (*svataḥ pramāṇa*). Truth is its own guarantee. Cognitions are by themselves valid and their validity can be set aside only by the contrary nature of their objects or by the recognition of discrepancies in their causes. When we are in doubt about the true nature of a thing perceived at a distance or in faint light, we can resolve the doubt by a second cognition obtained under improved conditions. Even in the most difficult cases we can obtain an absolutely true cognition after a series of three or four. Correspondence and coherence theories do not produce validity but only test it.

THE VEDĀNTA

The *Vedānta Sūtra* attempts to set forth the teachings of the Upanishads in a consistent way. Its short aphorisms are unintelligible by themselves. Many different systems ranging from pure non-dualism to explicit dualism attempt to interpret the *Sūtra*. The chief of them are those of Śaṅkara, Rāmānuja and Madhva.

Śaṅkara's Non-Dualism (Advaita).—Śaṅkara in his system asks whether there is anything in experience which may be regarded as foundational and discusses the claims of the different factors of experience to that title. Our senses may deceive us and our memory may be an illusion. The waking tracts may not be different from dream worlds, where also we visit places, handle shadows, and battle with ghosts. Though all objects of experience may be open to doubt, there is something which is beyond all doubt. Every one is conscious of the existence of one's own self and no one thinks "I am not." The self cannot be doubted or denied for "it is the essential nature of him who denies it." Though we cannot know it by thought, it does not entirely escape us. It is the object of the notion of self (*asmat-pratyaya viśaya*) and is known to exist on account of its immediate presentation (*aparokṣatvāt*). This self is distinct from the body, the senses, and the understanding. It is the principle of consciousness which is unaffected when the body is reduced to ashes and the mind perishes. It is one, universal and infinite.

Logical knowledge based on the distinction of subject and object is not final. The real excludes all relations, but logical knowledge is relational in character. The real simply is, but we attempt to characterize it in knowledge and no predicate is found adequate to it. In judgment, we equate the real with the unreal, the subject with the object. We attribute to the Ātman activity, agency and enjoyment. All our knowledge is strictly speaking non-knowledge (*avidyā*). The ascertainment of the ultimate reality by the exclusion of all that is imposed (*adhyasta*) on it is wisdom (*vidyā*). *Avidyā* is another name for our finitude. When its roots are cut our bondage is broken. Śaṅkara admits the reality of intuitional consciousness where the distinctions of subject and object are superseded.

Śaṅkara adopts the distinction between truth (*parāvidyā*) and empirical truth (*aparāvidyā*). The latter is not illusory or deceptive but only imperfect or relative. The empirical world is not self-existent or real. Yet there must be a reality on which it rests. Even if we regard the whole universe as merely imaginary there must be something which is the basis of all imagination. That reality is Brahman. As it is opposed to all empirical existence, it is given to us as the negative of everything that is positively known. We cannot even call it one (*ekam*). It is to be called non-dual (*advaitam*). It is the wholly "other" but not non-being.

When we are not content with such negative accounts we describe it as the personal God (*Īśvara*). God is the absolute cast through the moulds of logic.

Doctrine of Māyā.—Every object in the world tends to pass away from itself to something else. The categories of time, space and cause which bind experience are self-contradictory. Our knowledge of the world is inconsistent. When intuitional experience arises the pluralistic universe is sublated. The term *māyā* registers the imperfection and relativity of the world. It does not mean that the world is a mere illusion. Śaṅkara's refutation of Buddhist subjectivism is decisive on this question. While he traces the world to *avidyā* (ignorance) he takes care to point out that this ignorance is cosmic in character. The phenomenal self and the phenomenal world are mutually implicated facts. The mind with its categories on the one side and the world which it construes through them on the other hang together.

We cannot conceive the relation between the world and the absolute. The question of relation has meaning only if we have two "distincts," but the world is not distinct from Brahman. The finite is the infinite hidden from our view through certain barriers. When we intuitively recognize the absolute the relative disappears; when we discuss about the relative there is no absolute to which it has to be attached. The problem arises on account of a confusion of standpoints. If Brahman is to be viewed as the cause of the world it is only in the sense that the world cannot be explained apart from Brahman, though the latter is in no way touched by the world of appearance. Brahman is the basis of the apparent existence of the world (*vivartopādāna*).

The individual soul is different from the Ātman. Its divine nature is concealed by the external adjuncts (*upādhis*) of the sense organs and vital airs which form the subtle body. These, together with *karma*, accompany the soul in its migrations. *Mokṣa* or salvation is the lifting of the veil of ignorance which conceals from the soul the truth that it is and always has been one with Brahman. The road to realization lies not through something done or accomplished but through knowledge or the sweeping aside of the delusive veil of ignorance. Śaṅkara is clear that this insight cannot be attained without the discipline of moral life. Insight is not so much an answer to a riddle as a victory in a battle.

Rāmānuja's Theism.—Rāmānuja endeavours to show that the God of religious faith is not the unconditioned abstraction of Śaṅkara but a personal being whose reality need not be doubted simply because our knowledge of him is imperfect. The sense of personal communion with God involves a real fellowship with an other. The supreme Brahman has internal differences (*svagata-bheda*). Souls and matter are comprehended within the unity of the supreme as attributes to the substance or parts to a whole or body to the soul which animates it. Though attributes of God, souls and matter are in themselves substances possessing qualities with their own distinct modes, energies and activities. Souls, matter and God are different on account of their natural differences (*svarūpabheda*) but one on account of their identity (*aikyam*) of the modes and substance. Identity means only inseparable existence (*aprthaksiddhi*).

For Rāmānuja, causation is only an alteration of state. The creation of the universe from Brahman is not a production of something new but only a change of condition. It is a modification of that which is subtle into that which is gross. In the causal condition Brahman has for his body or mode the conscious (*cit*) and unconscious (*acit*) entities in their subtle form, while in the effect condition they are in a gross form.

Rāmānuja does not accept the explanation of the world and of the individual souls as mere productions of ignorance enveloping the nature of Brahman. If the multiplicity is due to human ignorance, then there should be no such world for God. But Scripture tells us of God's creation, etc., which means that God reckons with the world of multiplicity. We cannot regard the world as unreal, like the mirage, for while the activity prompted by the latter is unsuccessful, that based on the knowledge of the objects is successful. The reality of the world established by perception cannot be sublated by Scripture as the spheres of perception and Scripture are different. Simply because objects do not persist we can-

not conclude that they are unreal.

While for Śaṅkara, freedom consists in the removal of a barrier and the entering into the secure realization of a permanent and inalienable truth, for Rāmānuja, it is communion with God to be reached by devotion and faith. The individual is not effaced when the goal is reached but maintains his self-identity and enjoys the fruit of his faith in unending felicity.

Madhva's Dualism.—Madhva stands out for unqualified dualism and insists on the five great distinctions of God and soul, God and matter, soul and matter, one soul and another and one part of matter and another. Reality is of two kinds, independent (*svatantra*) and dependent (*paratantra*). God is the only independent reality; matter and souls are dependent. God controls souls and matter though he does not create or destroy. He is the efficient but not the material cause of the universe. Though absolutely dependent on Brahman, the individual souls are essentially active agents and have responsibilities to bear. While God is all-pervading, the souls are said to be of atomic size. They yet pervade the body on account of the quality of intelligence. No two souls are alike in character.

This brief sketch of Indian philosophy indicates the main lines of a singularly manifold philosophic development. It has been impossible to touch in this article on all the special points of interest or doctrinal variations. For these the student must consult special articles and treatises.

INDIAN PIPE (*Monotropa uniflora*), a saprophytic herb of the family Pyrolaceae, allied to the heaths, called also corpse-plant, American ice-plant and ghost-flower, found in moist, rich woods almost throughout temperate and warm North America and also in the Himalaya mountains and Japan. It is a smooth waxy-white plant, of unusual appearance, which grows on decaying vegetable matter and is somewhat parasitic on roots. The erect, usually clustered stems, 4 in. to 10 in. high, bear small scales representing leaves and terminate in a single nodding flower, about 1 in. long, blossoming from June to August, followed by a many-seeded capsule which becomes erect in ripening. Occasionally the flower, or more rarely the whole plant, has a pinkish or reddish tinge. All parts of the plant turn blackish in drying. There are two other species of the genus, both north temperate, one of which, *M. hypopitys*, the yellow bird's-nest or pine-sap, with flowers in a drooping cluster, widely distributed in Europe, Asia and North America, occurs in the British Isles.

INDIANS, NORTH AMERICAN: see NORTH AMERICA: *Ethnology*.

INDIAN SUMMER, a season of several weeks duration in late autumn in the United States characterized by a calm trans-

lucent atmosphere and mellow sunshine, in sharp contrast to climatic conditions which precede and follow it, especially in the northeastern States and the Mississippi valley. The haziness in the atmosphere is attributed to the smoke and dust floating in the still dry air, which absence of wind and rain makes possible. Indian summer is preceded by squaw winter, a cold spell when the thermometer first dips below the freezing point.

INDIA-RUBBER: see RUBBER.

INDICATOR. Many kinds of apparatus are included under this name, which, in general, implies a device to reveal conditions not otherwise apparent to the eye or hearing. Thus depths in a tank are indicated by a float, either showing a rod above, or moving a chain over a pulley and sliding a pointer down the outside. The depth of a cage in a mine is revealed at the winding-engine by a huge dial marked with figures, or in electric winders on a vertical scale with pointers travelling up and down. A scale is used to indicate the radius of a crane jib. Big dials on rolling-mills show the distance apart of the rolls in inches and fractions.

Some machines have indicators to signify when a certain quantity of work has been turned out. In others a bell rings when an automatic mechanism has used up a supply of raw material. A danger signal may be given by a bell in case of excess temperature. The copious forced oil-supply for the massive bearings and pinions of a rolling-mill has an alarm bell that rings should the circulation fail. A *gas leak indicator* is a very sensitive instrument, which will instantly show the presence of gas by the moving of a hand on a dial. Direction of movement is shown on some indicators where risk might arise through a misunderstanding on this point. A *speed indicator* is a small instrument with a point to press against the end of a shaft, or a roller against a rim, to show the speed; or it is a permanently fixed apparatus to indicate a rotational speed of an engine or machine, or the travelling speed of a vehicle. A *test indicator* is used in machine-tool practice. It magnifies the movement of a button-ended spindle to make records in thousandths of an inch on a dial; very fine deviations from truth are thus indicated in the parts of machines or work, or differences in thicknesses of components can be rapidly gauged in a sort of caliper, one anvil of which is at the end of the indicator spindle.

The pressure in the cylinder of a steam or explosion engine, or in a pump, compressor, or hydraulic machine, is ascertained with an indicator. This has a rotating drum turned by the pull of a cord from the cross-head (or in some cases the crankshaft)

STEAM ENGINE INDICATOR. USED TO TRACE THE VARYING PRESSURES IN AN ENGINE CYLINDER AND ENABLE THE HORSE-POWER TO BE CALCULATED

of the engine. Paper is wrapped round the drum, and a pencil connected by levers to a piston in a small cylinder traces a diagram on the paper as the drum turns. A spiral spring of known strength is placed above the piston and the cylinder is connected by a pipe to the engine cylinder. The varying pressures in the latter therefore affect the pencil accordingly. The diagram is measured to ascertain the mean effective pressure, and from this the I.H.P. (indicated horse-power) can be calculated. Refined developments have taken place in indicators for high-speed engines, including electrical recording, and optical types, which latter

use a beam of light, tracing a diagram on a photographic plate.

INDICATORIDAE: see HONEY-GUIDE.

INDICATORS, in chemistry, are substances which are used, in virtue of colour changes which they undergo, in order to show when a certain reaction has reached completion, or to give information as to the acidity of a solution (see also CHEMISTRY: *Analytical*). Thus, if a solution of a neutral chloride is being titrated with silver nitrate, a few drops of potassium chromate solution are added; as soon as all the chloride has been precipitated as silver chloride, the next drop of silver nitrate will form silver chromate (which is much less insoluble than silver chloride, but still fairly insoluble), and the precipitate will assume a faint reddish tinge whilst the liquid acquires a dull colour in place of the clear golden-yellow tint.

The indicators in general use may be divided into two classes (a) internal, and (b) external; for convenience, a large number of internal indicators used for determining acidity are dealt with as a separate class in HYDROGEN ION CONCENTRATION.

The potassium chromate in the above example is an internal indicator, because it is added to the solution undergoing titration with which it does not interfere. In titrating a solution of a ferrous salt by potassium dichromate, a very dilute solution of potassium ferricyanide is a useful indicator, but this has to be used externally, because, not only would it interfere chemically with the titration if used internally, but its colour changes could not be seen in the deep green solution. A drop of the titrated fluid is therefore withdrawn on a glass rod from time to time and mixed with a drop of the indicator solution on a white tile. As the titration approaches completion, the deep blue precipitate produced by the early drops gives place to a deep blue coloration, then pale blue, then green, then a slight dirty green, and finally no change at all, thus showing that the last trace of ferrous salt has been oxidized.

(a) Further examples of internal indicators are ferric alum in the titration of silver salts by thiocyanates (red coloration produced by the first drop in excess); starch solution in all iodometric titrations (blue while the least trace of iodine is present); methylene-blue in titrations with Fehling's solution (decolorized as soon as all the latter solution is reduced); diphenylamine, with phosphoric acid, in dichromate-iron titrations (purplish-blue with first drop of dichromate in excess); potassium thiocyanate in iron-titanous chloride titrations (red whilst any ferric iron remains).

(b) Other external indicators are uranyl acetate in the titration of zinc salts by phosphates (brown precipitate as soon as the latter is in excess); potassium ferrocyanide in the titration of phosphates by uranyl acetate (brown precipitate with slightest excess); potassium iodide and starch in titrations involving nitrites or Fehling's solution (blue with a trace of either); ferrous thiocyanate with Fehling solution titrations (red until all the Fehling solution has been reduced); tannin solution in the titration of lead salts by ammonium molybdate (brownish-yellow colour with excess of the latter). (A. D. M.)

INDICTION, a period or cycle of 15 years, the origin of which is obscure. It is thought to have originated in Egypt in A.D. 312, the year of the defeat of Mascentius. The assessment and dating of Roman tax censuses took place every 15 years (the "indiction" period), and became a recognized form of reckoning during the Middle Ages, particularly in Ecclesiastical affairs. See CHRONOLOGY and EGYPT.

INDICTMENT, in law, a formal accusation in writing laid before a grand jury and by them presented on oath to a court of competent jurisdiction. In England the accusation is drawn up in the form of a "bill" of indictment, prepared by the officer of the court or the legal adviser of the prosecution, engrossed on parchment or durable paper, and sent before the grand jury. The grand jury hear in private the witnesses in support of the accusation (whose names are endorsed on the back of the bill), and, if satisfied that a *prima facie* case has been made out, find the bill to be a true bill and return it to the court as such. If otherwise, the jury ignore the bill and return to the court that they find "no true bill." Indictments differ from presentments, which are made

by the grand jury on their own motion and their own knowledge; and from informations, which are instituted on the suggestion of a public officer without the intervention of a grand jury.

An indictment lies for "all treasons and felonies, for misprision of treasons and felonies and for all misdemeanours of a public nature at common law." And if a statute prohibit a matter of public grievance or command a matter of public convenience all acts or omissions in disobedience to the command or prohibition of the statute are treated as misdemeanours at common law, and unless the statute otherwise provides are punishable on indictment. In other words, the ordinary common law remedy in respect of criminal offences is by indictment of the accused and trial before a petty jury; and except in the case of informations for misdemeanour and summary proceedings by a court of record for "contempt of court" it is the only remedy, except where a statute creates another remedy, e.g., by trial before a court of summary jurisdiction.

Until the mitigation of the draconic severity of the English law in the early part of the 19th century, little or no power existed of amending defective statements or indictments, and the courts *in favorem vitae* insisted strictly on accurate pleading and on proof of the offences exactly as charged. Since 1827 numerous enactments have been passed for getting rid of these technicalities, which led to undeserved acquittals, and from 1851 the courts had power to disregard technical objections to the form of indictment and to amend in matters not essential in case of variance between the indictment and the evidence.

The difficulties and technicalities of criminal pleading were finally dealt with by the Indictments Act 1915, which made rules as to indictments and set up a rule committee under the lord chief justice having power to vary or annul the rules in the statute and make further rules germane to the subject.

By that act it was provided (s. 3) that "every indictment shall contain, and shall be sufficient if it contains, a statement of the specific offence or offences with which the accused person is charged, together with such particulars as may be necessary for giving reasonable information as to the nature of the charge." Again, by s. 4, "subject to the provisions of the rules under this act, charges for more than one felony or for more than one misdemeanour, and charges for both felonies and misdemeanours, may be joined in the same indictment, but where a felony is tried together with any misdemeanour, the jury shall be sworn and the person accused shall have the same right of challenging jurors as if all the offences charged in the indictment were felonies."

Power is given before or at any stage of the trial to amend a defective indictment, if it can be done without injustice; to order the separate trial of separate offences if the accused would be prejudiced or embarrassed; or to postpone a trial for amendment or separate hearing. By the Vexatious Indictment Act, 1859 (save as therein excepted), no bill of indictment can be presented to the grand jury for the numerous offences to which it applies, unless (a) the person presenting it has been bound by recognizance to prosecute or give evidence; or (b) the accused has been committed to or detained in custody or has been bound by recognizance to answer the indictment; or (c) unless it is preferred by the direction or consent of certain high legal authorities. The act has since been extended to other offences.

In Scotland the terms indictment or criminal letters are used to express the *acte d'accusation*. But except in the case of high treason there is no grand jury, and the indictment is filed like an English criminal information by the lord advocate or one of his deputies: and it is only by order of the court of justiciary that a prosecution can be instituted without the general assent of the lord advocate. By the Criminal Procedure Scotland Act 1887 the form of Scots indictments is much simplified. (X.)

United States.—As a general rule, the indictment must charge but one crime and in one form, but the crime may be charged in separate counts to have been committed in a different manner or means; and where the acts complained of may constitute different crimes such crimes may also be charged in separate counts.

The form of the indictment varies more or less in the different States, because of particular constitutional or statutory

provisions. In many States the form is prescribed by statute, the object of which is to simplify the form and to do away with the strictness formerly required by law.

Since an indictment is a finding by the grand jury upon oath, and depends, for its validity, upon that fact among others, it could not, until recent times, be amended by the court without the concurrence of the grand jury that presented it. Under modern statutes, however, mistakes in the statement of time or in the name or description of any place, person or thing, may, in the discretion of the court, be cured by amendment at the trial upon such terms as the court may deem reasonable.

So, under modern statutes, an indictment is good if the crime charged is stated with such a degree of certainty as to enable the defendant to prepare his defence and the court to pronounce judgment, upon conviction, according to the rights of the case and to prevent a second prosecution for the same offence. It is not regarded as insufficient by reason of any imperfection in matter of form, which does not tend to the prejudice of the substantial rights of the defendant upon the merits.

The U.S. Constitution declares that "No person shall be held to answer for a capital or otherwise infamous crime, unless on presentment or indictment of a grand jury." This provision applies only to prosecutions in the Federal courts. But, in many of the State Constitutions, there is a similar provision applying to prosecutions in the courts of such States. Under such a constitutional provision an indictment is absolutely essential to the jurisdiction of the court to try the offender, and the accused cannot even waive the benefit of the provision by consenting to be tried without such. The court of appeals of the State of New York has recently held that a statute, which purports to permit one charged with a capital or otherwise infamous crime to plead guilty without an indictment having first been found against him, is unconstitutional as violative of the Constitution of that State.

But where the Constitution does not require an indictment, there is nothing to prevent the legislature from providing for prosecution of all crimes, even capital, by some other mode of accusation; as, e.g., by information, which is a written accusation of crime preferred by the prosecuting officer without the intervention of a grand jury. And, in some States, such statutes have been enacted.

(J. H. BA.)

"INDIES, LAWS OF THE," in the colonial history of Spain, a general term for (1) certain codes for the colonies listed below, and especially the compilation of 1680; or (2) the whole body of colonial law, made up of a multitude of royal *cédulas*, orders, letters, ordinances, provisions, instructions, *autos*, dispatches, pragmatics and laws—all emanating from the crown (or crown and *cortes*) and all of equal force—that were passed through to officers and branches of the colonial administration, or between the departments of government in Spain. The transfer of Spanish law to *Ultramar* began with the Conquest; and especially the civil law was translated with comparatively slight alteration. Many things, however, peculiar to colonial conditions—the special relations of the crown and the papacy in America, the "divisions of lands" and "commendations" (a system of patronage, or modified slavery) of the Indians, the development of African slavery, questions of natural and international law, the spread of discovery and administrative areas, the sales and grants of public lands—necessitated organizing the general doctrine and a vast quantity of administrative applications, into a body of special law. The general doctrine was applicable everywhere in *Ultramar*, and difficult and inconstant communication and other considerations early counselled some codification. This was begun in Mexico in 1525; a volume was published in 1563, and other inadequate compilations in 1596 and 1628, finally the great *Recopilación de Leyes de los Reinos de las Indias* of 1680. This code has received even extravagant praise. But its minute administrative strangulation of colonial political life and its monopolistic economic principles were serious defects. Two centuries in formation, the code of 1680 was only one century in effect; for in the 1760's Charles III. began to break down the monopolistic principles of colonial commerce. This came too late to save the mainland colonies in America, but it aggrandized Cuba. It is there (also

in Porto Rico and the Philippines) that the later history of the Laws of the Indies (see CUBA) are to be found.

BIBLIOGRAPHY.—Of the *Recopilación* of 1680, five editions were issued by the government, the last in 1841 (Madrid); and there are later, private editions approved by the government. See also J. M. Zomora y Coronado, *Biblioteca de legislación ultramarina* (Madrid, 1844-49); J. Rodríguez San Pedro, *Legislación ultramarina concordada*, covering 1837-68 (Madrid, 1865-68); the *Boletín oficial del Ministerio de Ultramar*, covering 1869-79; and M. Fernández Martín, *Compilación legislativa del gobierno y administración civil de Ultramar* (Madrid, 1886-94); for Cuba 1854-98, see the series of *Reales Ordenes . . . publicadas en la Gaceta de la Habana* (Havana, 1857-1898).

INDIFFERENTISM in philosophy has several partly disconnected and partly opposed meanings. (1) In Scholastic Logic it means the view that objects are neither particular only nor universal only, but are indifferently particular or universal according to the point of view from which they are regarded. This view was held by Adelard of Bath (about 1200) and others. (2) In the history of ancient philosophy "indifferentism" is used to denote the view common to the Stoics, Sceptics and Cynics, that all things are a matter of indifference except virtue, which is the only thing that has intrinsic worth. (3) Sometimes the term is employed to indicate the view that nothing has any intrinsic value, not even the moral life, all things being essentially "indifferent," that is ascologically neutral.

INDIGEN, the horticultural term applied to a plant species or form which originated in a natural habitat in distinction from cultigen (*q.v.*), a plant form originated in cultivation.

INDIGO, one of the most important and valuable of all dye-stuffs, until about 1890 was obtained entirely from plants, mainly those of the genus *Indigofera* (Leguminosae) of which the *I. sumatrana* and *I. arrecta* have been most important, though in China the *Polygonum tinctorium*, and in West Africa the *Lonchocarpus cyanescens* find use for this purpose. In Europe, to the middle of the seventeenth century, the woad plant *Isatis tinctoria* was entirely used for the application of indigo to textile fabrics. Owing to the lower cost of the synthetical dye, natural indigo for export is now manufactured in but small amount, and almost entirely in Bengal. The plant, which is reared from seed sown in April, is cut down in June, a second crop being obtained therefrom in August. The indigo-yielding principle, present mainly in the leaf, is the glucoside *indican*, $C_{14}H_{17}NO_6 \cdot H_2O$, which is readily soluble in water. This, by the action of an enzyme also present in the plant, is transformed into glucose and *indoxyl*, C_8H_7NO , and the latter (also colourless), in contact with air, becomes oxidized with the production of indigo, $C_{16}H_{10}N_2O_2$ (see GLUCOSIDES, NATURAL).

The plant is cut early in the morning and at once transported to the factory. Here it is steeped in water for 9-14 hours in large vats, when, under the joint influence of the enzyme and of bacteria, the indican is transformed into indoxyl. The extract is now transferred to "beating" vats, which lie at a lower level, and is there submitted to intimate contact with air, employing a paddle (or so-called "beating") wheel, or a steam injector. Conversion of the indoxyl into indigo thus occurs, which settles and is collected, boiled with water, well drained, pressed into moulds, and dried at the ordinary temperature. Though the introduction of more scientific methods into the manufacture of the natural product has effected various improvements, this industry has continued to decline, and is now of minor importance. (See also DYES, SYNTHETIC.)

(A. G. P.)

INDIGO-BIRD (*Cyanospiza cyanea*), a North American bird of the finch family (*Fringillidae*), breeding chiefly in the north-eastern United States and adjacent Canada, but extending westward to Colorado and Texas. The adult male is of a deep blue nearly all over, changing to brownish in the autumn. The female is brown above and ochreous-white beneath.

INDIUM, a soft malleable metal about as heavy as tin. Chemically it is an element (symbol In, atomic number 49, atomic weight 114.8) included in the periodic group containing aluminium, gallium and thallium (see PERIODIC LAW). It melts at 155° C and vaporizes above 1,450° C. Its specific gravity is 7.2 to 7.42 and its specific heat 0.05695. Indium was discovered in the zinc blende of Freiberg in 1863 by F. Reich and Th.

Richter, who detected in the spectroscope the strong indigo-blue line (λ 4,511) in its spectrum (Latin, *indicus*, Indian; cf. indigo). It is one of the very rare elements, occurring only in small quantities in zinc blende. It is best obtained from commercial metallic zinc, which contains small amounts of indium, by treating the metal with insufficient hydrochloric acid for complete solution, whereby indium is precipitated on the undissolved zinc. The metallic residue is dissolved in nitric acid, the solution evaporated with excess of sulphuric acid and treated with ammonia, when indium and iron hydroxides are precipitated. These hydroxides are redissolved in hydrochloric acid and boiled with excess of sodium bisulphite, when basic indium sulphite is precipitated. These processes are repeated to obtain pure indium sulphite. Indium is also separated from a mixture of anhydrous chlorides by addition of alcoholic pyridine, when the complex salt $\text{InCl}_3 \cdot 3\text{C}_5\text{H}_5\text{N}$, is precipitated.

Indium oxide, In_2O_3 , a yellow powder formed by igniting the hydroxide, is readily reduced on being heated with carbon or hydrogen. The hydroxide, $\text{In}(\text{OH})_3$, a gelatinous precipitate thrown down by adding ammonia to any soluble indium salt, is readily soluble in caustic soda or potash but not in ammonia. Three chlorides are known: (1) The trichloride, prepared by the action of chlorine on the metal or of chlorine and carbon or sulphur on the oxide, is a soluble deliquescent salt; its vapour density corresponds with InCl_3 . (2) The dichloride, InCl_2 (vapour density normal at $1,300^\circ\text{C}$), prepared by the action of hydrogen chloride on the metal. (3) The dark red monochloride, InCl (vapour density normal at $1,100^\circ\text{C}$), obtained by distilling the dichloride over sodium. The di- and mono-chlorides are both decomposed by water to give the trichloride and indium.

The salts of indium correspond in type with the trichloride; among them are the indium alums, $\text{R} \cdot \text{In}(\text{SO}_4)_3 \cdot 12\text{H}_2\text{O}$, where R is NH_4 , Rb or Cs. Indium sulphide, In_2S_3 , is obtainable by direct combination of indium and sulphur as an infusible red mass, or as a yellow precipitate on passing sulphuretted hydrogen into a solution of an indium salt; it dissolves in concentrated acids. Indium acetylacetone, $\text{In}(\text{C}_5\text{H}_7\text{O}_2)_3$, colourless prismatic crystals, melts at 186°C and sublimes with partial decomposition. It exhibits isomorphous relationships with the acetylacetones of aluminium, gallium, iron and scandium (G. T. Morgan, H. D. K. Drew and T. V. Barker, 1921) and is obtained by dissolving freshly prepared indium hydroxide in acetylacetone.

BIBLIOGRAPHY.—R. E. Meyer, *Das Indium* (1868); P. E. Browning, *Index to the Literature of Indium* (1905); J. W. Mellor, *Comprehensive Treatise of Inorganic and Theoretical Chemistry*, vol. v. (1924).

INDIVIDUALISM, in political philosophy, the theory of government according to which the good of the State consists in the well-being and free initiative of the component members (Lat. *individualis*, that which is not divided, an individual). From this standpoint, as contrasted with that of the various forms of Socialism (*q.v.*) which subordinate the individual to the community, the community as such is an artificial unity. Individualism is, however, by no means identical with egoism, though egoism is always individualistic. An individualist may also be a conscientious altruist: he is by no means hostile to or aloof from society (any more than the Socialist is necessarily hostile to the individual), but he is opposed to State interference with individual freedom wherever, in his opinion, it can be avoided. The practical distinction in modern society is necessarily one of degree, and both "Individualism" and "Socialism" are very vaguely used, and generally as terms of reproach by opponents. See ANARCHISM; CAPITALISM; ECONOMICS; SOCIALISM.

INDIVIDUALITY. The individuality of organisms is a difficult problem of scientific philosophy. The common view is that each obviously separate organic entity is an individual—man, cow, beetle, oak-tree, cabbage. But difficulties arise when we take lower organisms into account, and look deeper into life-history. Many animals such as polyps form colonies whose members are attached to a common living stem. All gradations occur between single polyps, those forming temporary colonies by budding, and those with permanent colonies. In permanent colonies, all members may be alike, or there may be division of labour

among different types. In extreme cases the colony behaves as a single unit (Portuguese man-o'-war and other Siphonophora), the members being entirely subordinate. (See COELENTERATA.)

The units of the colony are here themselves compound, consisting of many cells: but a parallel series occurs with single-celled units. The Protozoa (*q.v.*) are typically single, free-living cells. A number are colonial, and a few colonial forms (e.g., *Zoothamnium*) exhibit division of labour, one or two (e.g., *Volvox*) being co-ordinated to move as wholes. The same type of problem, but in exaggerated form, arises in regard to symbiotic organisms. (See SYMBIOSIS.) What we call a termite is an obligatory partnership between an insect, the termite proper, and protozoan inhabitants of its intestine which digest wood for the partnership. A lichen (*q.v.*) is a compound of a fungus and a green alga.

Equal difficulties arise with regard to reproduction and regeneration. All organisms are part of a continuous stream of life, the offspring taking origin from a piece of living substance detached from its parent or parents. The individual can therefore never be sharply delimited from the stream of life, any more than an eddy from the river. In higher animals each fertilized egg normally gives rise to a single organism; but exceptionally it divides, wholly or partially, during early stages. When it divides completely, so-called "identical" twins result; common-sense calls these two individuals. But all gradations are found between this condition, slight union as in the Siamese twins, intimate union, and various states of partial doubling. Similar partial and total duplications can be artificially produced in lower organisms. (See REGENERATION; EXPERIMENTAL EMBRYOLOGY.)

Hitherto we have been implicitly considering the organism as stable; but in reality no organism is at all stable—even the longest-continued adult stage is but part of a changing life-cycle. We are accustomed to think of ourselves as the same individual which we were as a child, and to extend this identity backwards to embryo and egg. This is legitimate, but involves a rather new conception of individuality. The individual thus viewed ceases to be a static *being*; it is rather, as Le Dantec says, a *history*. What breaks in this history suffice to justify us in saying that a new individual has arisen? In higher animals there are no very abrupt changes from egg through embryo to adult. In frogs the change at metamorphosis (*q.v.*) is so violent that two states receive different names—tadpole and frog. In higher insects, the organs of the grub are actually broken down during pupal life, and those of the adult arise from rudiments previously dormant. In sea-urchins the adult arises as a separate lateral rudiment in the late larva; and in Nemertina (*q.v.*), the bulk of the larva is actually thrown off at metamorphosis.

We generally call such cases transformations of a single individuality; but there is no hard line to be drawn between them and other cases, e.g., liver-flukes (see TREMATODA), whose life-cycle consisted of a whole succession of forms, which here we usually style separate individuals. Finally, there are difficulties concerned with dedifferentiation (*q.v.*). A sea-squirt such as *Clavellina* dedifferentiates to an opaque simply-constructed mass, then redifferentiates to a normal *Clavellina*. Is it the same individual, or a new one?

In plants, difficulties are even greater, since often there is no definitely shaped body, but only a tangled felt of filaments, e.g., some Algae, most fungi. Mushrooms are only fructifications; the plant's vegetative business is performed by a subterranean felt-work of wholly irregular construction. Even in higher plants this sort of thing may hold. Many trees grow by suckers, so that one "individual" may be in organic connection with several others. The climax is reached in the case of the banyan tree, in which the branches let fall aerial roots which turn into new trunks, so that a many-trunked colonial tree is produced.

These examples will show the impossibility of defining an individual in any absolute way, or of believing that individuality is ever complete or perfect. We must rather say that there are degrees of individuality, and that it is very poorly exhibited by plants and many animals.

An individual must be in some degree a unitary whole with interdependence of parts; it must have a history of appreciable

duration, singleness and continuity; it must be rather sharply marked off from other individuals; its working must be directed at least partly to continuing either itself or other systems like itself. In so far as portions of living substance exhibit these characters, they are individuals. The more definite the unity, the more obvious its continuity, the greater the interdependence of its parts, the greater its independence as a whole, the more individuality must we ascribe to it.

During the course of evolution, two, in a sense contrary, tendencies have been at work—*aggregation* and *individuation*. Individuation is the tendency towards making a given unit more of an individual. Aggregation is the tendency to fit together a number of individuals to make an aggregate, or unit of higher order (which may then be progressively individualized). We can distinguish individuals of three orders or grades. The lowest are single cells, e.g., free-living protozoa, bacteria. These first-grade units may become aggregated to form colonies; the colonies may show division of labour between their cellular units and may even be so co-ordinated as to behave and move as wholes (e.g., *Volvox*). When this stage is reached, we may properly speak of a second-order individual. All multi-cellular animals are second-order individuals: and the evolutionary history by which a simple coelenterate has been transformed into specialized creatures like insects or mammals is the history of the individuation of such units. These units, however, may again undergo aggregation. Colonies without division of labour are seen in Polyzoa, corals, etc.: colonies with some division of labour are frequent among hydroid polyps; and colonies which can be called third-order individuals are found in siphonophores.

The bonds holding the parts of such units together are physical; but with the development of efficient sense-organs and brains, the parts can be held together by psychical bonds. This, without division of labour, is seen in gregarious animals; with division of labour, in the communities of social insects and of man, which thus also are incipient third-grade individuals.

As a general rule, where a unit of higher grade acquires more individuation, the lower-grade units composing it become less independent and more subordinate, and so lose individuality. The only exception to this occurs in human communities, in which the presence of language and conceptual thought has transformed the method by which the second-grade individuals (men and women) enter into relation with each other and with the whole.

In man for the first time mental life can become organized into a continuing unity with interdependent parts. Superposed upon (but interwoven with) the physical individuality is the mental individuality, which we call *personality*. Obviously degrees of individuation of the personality are possible, both as regards the integration of the different emotional tendencies and the intensity to which any one capacity is developed.

It is not necessary that personality should be intensified by living in a highly-organized society—indeed, the reverse is often the case—but it is true that only in highly-organized societies do the highest levels of individuation become possible. High degree of individuation undoubtedly seems to be a progressive characteristic of life. It is thus important to notice that the individuation attained by the state or any other human community is, and apparently must always remain, far lower than that possible to its component members; and that therefore, biologically speaking, the community exists for the individual more than the individual for the community. Since both, however, are intimately interdependent, there are, from the purely biological point of view, many cogent duties of the individual to the community.

What we have said about the aggregation of similar units to form units of higher grade, applies also to the aggregation of dissimilar units, as in the development of symbiosis (*q.v.*). The only differences are that a good deal of division of labour is already given from the start in the difference between the two symbiotic species, but that their difference and separateness makes progress towards a higher degree of intimate union and mutual integration very difficult.

The idea of absolute individuality must thus be given up, just as much the idea of definite and unchanging objects in the

inorganic world. A stone, e.g., is continuously losing or gaining matter and energy to or from its surroundings, and it is not the same to-day as yesterday. It is relatively but not absolutely distinct from the rest of the world. So the individual is relatively separate, unified and independent, but never absolutely so. Among animals, the highest degree of individuation is found among second-grade units, but the greatest biological success is achieved by the combination of these to form third-grade units of low individuation (social insects, man).

Man's mental powers make it possible for him to merge his individuality with that of other individuals, with that of the community, and with general ideas; or, as it is often justly put, to lose his own individuality in something other, greater, or higher than himself.

The mental individuality (personality) is integrated out of a number of relatively separate emotional tendencies and systems of ideas; besides the central well-integrated portion, which alone has the right to be called personality, there exists a fringe of loosely-connected or unconnected mental life, and also subterranean systems of ideas gathered round emotional tendencies which have been repressed instead of integrated with the rest. (See *PSYCHOLOGY*.) Peculiar sudden enlargements of mental individuality may occur if these unintegrated or repressed systems are brought into connection with the main personality. Conversely, certain conflicts may terminate in a total splitting of the personality into two or more parts—a process analogous to the reconstitution of the halves of a bisected planarian or other low animal into complete individuals. (See *REGENERATION*.)

Paradoxically, the mental individuality attains its highest development only by entering into relation with the greatest possible number of facts and ideas outside itself (though it must of course organize them within its own system into a unified whole). If physical individualities are never at all completely separate or independent physically, mental individualities can only develop by the mutual interpenetration of subject and object in experience. Many ideas bearing on this last point of view will be found in A. N. Whitehead, *Science and the Modern World*.

INDO-ARYAN LANGUAGES. This term applies to the members of the Indo-European family of languages which are spoken in India at the present time. They are all *Satem* languages.

Classification.—The oldest specimens of Indo-Aryan speech very closely resemble the oldest Iranian. The development of the two old forms of speech went on independently and followed somewhat different lines. This is most marked in the treatment of a nexus of two consonants. While modern Iranian often retains the nexus with little or no alteration, modern Indo-Aryan prefers to simplify it.

The earliest extant literary record of Indo-Aryan languages is the collection of hymns known as the *Rig-Veda* which probably contained many dialectic variations. As we have it now, we may take it as representing, on the whole, the particular vernacular dialect spoken in the east of the Punjab and in the upper portion of the Gangetic Doab. Later it extended between the Punjab and the modern Allahabad from the Himalayas to the Vindhya hills in the south, over the area known to Sanskrit geographers as the *Madhyadēśa* or *Midland*, also called *Āryāvarta*, or the "home of the Aryans." Here it received constant literary culture, and a refined form of its archaic dialect became fixed by the labours of grammarians about the year 300 B.C., receiving the name of *Saṁskṛta* (Sanskrit) or "purified," in contradistinction to the folk-speech of the same tract and to the many Indo-Aryan dialects of other parts of India, all of which were grouped together under the title of *Prākṛta* (Prakrit) (*q.v.*) or "natural," "unpurified." Sanskrit (*q.v.*) became the language of religion and polite literature, and thus the Midland, the native land of its mother dialect, became accepted as the true pure home of the Indo-Aryan speech.

Dialectic Variations.—In the time of Asoka (250 B.C.), there were at least three dialects, an eastern, a western and another in

the extreme north-west. The grammarian Patañjali (150 B.C.) mentions the existence of several dialects.

Round the Midland, on three sides—west, south and east—in Vedic times, Indo-Aryan dialects were spoken which were all more closely related to each other than was any of them to the language of the Midlands. Thus, at an early period of the linguistic history of India there were two sets of Indo-Aryan dialects—one the language of the Midland and the other that of the dialects which form an Outer Band.

As time went on, the people of the Midland conquered the eastern Punjab, Rajputana with Gujarat (where they reached the sea) and Oudh. Hence in all these territories we now find mixed forms of speech. The basis of each is that of the Outer Band, but the body is that of the Midland. As we leave the Midland and approach the external borders of this tract, the influence of the Midland language grows weaker and weaker, and traces of the original Outer language become more and more prominent. In the same way the languages of the Outer Band were forced farther and farther afield over the Maratha country, into Orissa, into Bengal and, last of all, into Assam.

At the present day, a Midland Indo-Aryan language (western Hindi) occupies the Gangetic Doab and the country immediately to its north and south. Round it, on three sides, is a band of mixed languages, Punjabi (of the central Punjab), Gujarati, Rajasthani (of Rajputana and its neighbourhood), and eastern Hindi (of Oudh and the country to its south). Beyond these again, are the Outer Languages (Kashmiri, with its Dardic basis), Lahnda (of the western Punjab), Sindhi (here the band is broken by Gujarati), Marathi, Oriva (of Orissa), Bihari, Bengali and Assamese. The Pahari languages in the Himalaya, north of the Midland belong to the Intermediate Band, being recent importations from Rajputana, while Kohistani includes the mixed dialects of the Sivat and Indus Kohistans. The Midland language is therefore now enclosed within a ring fence of intermediate forms of speech.

INDO-CHINA, FRENCH. The geographical denomination of French Indo-China includes the protectorates of Annam, Tongking and Cambodia, the colony of Cochinchina and part of the Laos country. In 1900 the newly-acquired territory of Kwang-Chow bay, on the coast of China, was placed under the authority of the governor-general of Indo-China. French Indo-China, the eastern portion of the Indo-Chinese peninsula, lies between 8° 30' and 23° 25' N. and 100° and 109° 20' E. It is bounded north by an arbitrary line which separates it from China, east and south-east by the Gulf of Tongking and the China sea; west by the Gulf of Siam and Siam, and north-west by Burma. The area is 274,385 sq.m., with a population of 19,636,137, of which 26,137 are Europeans. Indo-China is made up of several very distinct regions; two great deltas (that of the Song-Koi, which forms Tongking, and that of the Mekong, forming Cochinchina and part of Cambodia), and between them the Cordillera of Annam. To the west of this chain lie the mountainous continental regions of Laos. The relief of Indo-China is thus very uneven, the only plains being the deltas of Tongking (13,000 sq.km.) and of Cochinchina (40,000 sq.km.) and some small coastal plains. The north of the country is occupied by the mountain-

knob of Upper Tongking and Upper Laos, formed of calcareous plateaux and sandstone hills, whence arises the Cordillera of Annam, which curves parallel to the coast from the Gulf of Tongking to the delta of Cochinchina, sending out seawards buttresses which bound the enclosed bays of Annam. This mountain chain has a steep slope on the eastern side, but descends in steps on the western side to the plateaux of Laos. It is through

VIEW ON THE RIVER NEAR SAIGON SHOWING HOUSEBOATS OF THE POOR, AND SHACKS BUILT OUT OVER THE RIVER'S EDGE

this plateau country of Laos that the Mekong (*q.v.*) one of the longest rivers (1,900 m.) of south-east Asia descends in steps towards its delta. The Red river descends from the mountains of Yun-nan, rising near Tali-fu between deep and inaccessible gorges, and becomes navigable only on its entry into Tongking. Means have been taken to render it available to steam launches, and in consequence of an agreement between the State and the Compagnie des Correspondances Fluviales a service of steamers is provided from its mouth to Lao-Kay. Near Hung-Hoa the Red river receives its two chief tributaries, the Black river from the plateaux of the west—the land of the Muongs—and the Clear river, one of the largest of whose tributaries issues from the Ba-Be lakes. The Black river is navigable for a considerable distance, the Clear river only from Tuyen-Kwang. The general features of the climate, of soil and of relief, give to the rivers of Indo-China certain common characteristics; they are swollen in summer and low in winter in consequence of the monsoons; rapids and cascades play an important part in limiting navigation; their erosive activity is shown in the formation of deltas. The coasts reflect the general character of the relief, being low and muddy at the edge of the deltas, sandy along the coastal plains, and scarped and dissected at the points where the mountains reach the sea. In spite of the great length of coastline (1,560 m.) it is therefore not favourable to navigation.

Geology.—The geological history is still far from clear; the region seems to have been land in the Secondary period. In Late Tertiary times the mountain chains of Tibet, prolonged towards the east and compressed between the southern edge of the massif of China and the northern edge of the Deccan, gave rise to the confused mountain masses of Upper Tongking and Upper Laos. In the peninsula these chains spread out in two arcs, one of which, the Cordillera of Annam forms the backbone of French Indo-China. In the Quaternary, river-alluvium filled the gulfs and joined to Asia the islands which formed the nuclei of Tongking, Cambodia and Cochinchina. The geological formations belong to two main series, one Archæan and Primary, which constitutes the main mass of the mountains and of the plateaux (granite, schists and metamorphic limestone), and the Quaternary, making up the plains and deltas (continental alluvium). Recent eruptive rocks are found in the north of Saigon and in the south-west of the delta of Cochinchina.

Climate.—The climate of Indo-China is that of an inter-tropical country, characterized by a dry and a wet season, but with diversities due to differences of latitude, altitude and expo-

sure. Cochin-China and Cambodia have very regular seasons, corresponding with the monsoons. The north-easterly monsoon blows from about Oct. 15 to April 15 within a day or so. The temperature remains almost steady during this time, varying but slightly from 78.8° to 80.6° F by day, to 68° by night. This is the dry season. From April 15 to Oct. 15 the monsoon reverses and blows from the south-west; the season of daily rains and tornadoes commences; the temperature rises from 80.6° to 84.2°, at which it remains day and night. April and May are the hottest months (from 86° to 93.2°). The damp, unwholesome heat sometimes produces dysentery and cholera. The climate of Annam is less regular. The north-easterly monsoon which is "the ocean-wind," brings the rains in September. The north-easterly gales lower the temperature below 59°. September is the month in which the typhoon blows. During the dry season—June, July and August—the thermometer oscillates between 86° and 95°. The nights, however, are comparatively cool. Tongking has a winter season—October to May. The temperature, lowered by fog and rains, does not rise above 75.2° and descends to 50° over the delta, and to 44.6° and even 42.8°, in the highlands, where white frost is occasionally seen. The summer, on the other hand, is scorching. The wind veers to the south-east and remains there until October. The temperature rises to over 83°; often it reaches and continues for several days at 95° or even more. The nights are distressingly airless. The Laos country in the interior, and lying at a high altitude, is cooler and drier. Its deep valleys and high hills vary its climate.

Fauna and Flora.—The fauna is abundant and varied. The wild life of Laos includes elephants, rhinoceros, one- and two-horned (rhinoceros horn is employed as a "medicine"); rare as a result of hunting; tiger, panther, bears, monkeys and rats, among which is the *nu-khi*, or rat found in the rice-fields of the highlands, in which its ravages are considerable. In the mountain districts the leopard, wild boar and deer are found, and in the neighbourhood of habitations the tiger-cat and ichneumon. The buffalo is commonly found wild in Laos; as a domesticated animal it also holds a prominent place. The zebu bull is used for transport purposes. There is an indigenous race of horses, excellent in spite of their small size—the horses of Phu-Yen. Birds are numerous. Reptiles (apart from the caimans of the Mekong, which attain a length of over 30 ft., and are much appreciated by the Annamese as food) are extremely numerous and varied in species. The rivers are rich in fish. The sole is found in the rivers of Tongking. The Mekong is fished for two species peculiar to it—the *pa-beuk* and the *pa-leun*, which attain a length of nearly 6 feet. All varieties of mosquitoes, ants and leeches combine to render the forests bordering the Mekong impracticable. Peculiar species of grubs and caterpillars destroy the cotton and coffee plantations of Cochin-China. The silkworm may be said to be indigenous in Tongking, where there are several thousand acres of mulberry trees.

The flora is inter-tropical, and comprises nearly all the trees known in China and Japan. The bamboo is utilized in building and a variety of other ways. Teak was found some years ago in considerable abundance, and plantations of it have been made. Certain hard woods are used for marqueterie and other ornamental work. Rubber is also exploited. Cotton, previously cultivated in Cochin-China and Cambodia, gives excellent results in Laos and in Tongking. Tea, of which there are a certain number of plantations in the highlands of Tongking and Annam, grows wild in Upper Laos. Cocoa and coffee are cultivated in Tongking and Cambodia. Cinnamon and cardamoms are gathered in Laos and Annam. Ground nuts, sesame, sugar canes, pepper, jute, tobacco and indigo are also grown. Rice is incomparably the most important crop. All European fruits and vegetables have been introduced into Tongking, and with certain exceptions—the grape, for example—succeed perfectly.

People.—The population of French Indo-China is very heterogeneous, owing to the situation of the country, exposed to every invasion. The Annamese form the bulk of the population in Annam, Tongking and Cochin-China and four-fifths of that of the whole country; the Khmers or Cambodians; the Chams of

southern Annam; the Thais, including the Laotians; and the autochthonous tribes classed by the other inhabitants as Moïs or Khas ("savages"). The last-named representatives of the indigenous peoples, survive only as strays; they were driven into the interior by the now dominant races. In the north of Tongking people of Laos origin occur—the Thōs round Kaobang, the Muongs in the mountains bordering the Red river. When mixed with Chinese the Muongs and the Thōs are known as the Hung-dans, Māns and Miens. The Muongs are bigger and stronger than the Annamese, their eyes often almost straight. They have square foreheads, large faces and prominent cheekbones. In the centre and south of the Indo-Chinese mountain chain are found, under a multiplicity of names, people of Malayan origin mixed with all the races of Indo-China. Laos is inhabited by an essentially miscellaneous population, falling into three main groups—the Thais; various aboriginal peoples classed as Khās; and the Moos and the Yaos, tribes of Chinese origin. (For general anthropology of this area see the section devoted to anthropology of Further Asia in the article ASIA.)

Religions.—The Annamese religion is a somewhat vague and very tolerant Buddhism, which in practice resolves itself chiefly into the worship of ancestors. Certain ceremonies performed in Cambodia resemble distantly the Brahmanical cult from which they are derived. The Roman Catholic religion has been introduced by missionaries. There is an apostolical vicariate in Cochin-China, one in Cambodia and several mission stations in Tongking.

Administration.—Indo-China, or rather the Indo-Chinese Union, is not, properly speaking, a colony; it is an administrative scheme which comprises a colony (Cochin China), four protectorates (Annam, Tongking, Cambodia and Laos), and a special territory (Kwangchow-Wan). Originally Cochin-China, the only French possession in the peninsula, was a colony directly administered like other colonies, by the Ministry of Marine. As further conquests were effected, Tongking, Annam and Cambodia were subjected to the régime of a protectorate somewhat ill-defined, and in 1887 these territories were grouped together under the governor-general of French Indo-China. In 1893 the group was enlarged by the inclusion of Laos and, in 1898, by that of Kwangchow-Wan. The government of the colonies having been transferred (1889) from the Ministry of Marine to the Ministry of Commerce, and in 1894 to the newly-created Ministry of the Colonies, the control of the residences passed gradually into the hands of civil agents. Cochin-China, which already, by the decree of Feb. 8, 1880, had been endowed with a colonial council, had a municipality, a chamber of commerce and even a deputy in the French parliament. Indo-China is administered by a governor-general, who resides sometimes at Hanoi sometimes at Saigon. The functions and powers of the latter official were, however, but vaguely defined before the decree of April 21, 1891. The residents-general of Tongking, Annam and Cambodia, and the lieutenant-governor of Cochin-China, as well as the military authorities, were placed under him. But this change of policy, which put an end to the system of expeditions and minor military operations, and restricted the power of the residents whilst restoring to the mandarins a share of authority, was unwelcome to numerous interests, which, combining, secured the abrupt recall of M. de Lanessan, first governor-general, on Dec. 29, 1894. The decree of April 21, 1891, was not revoked, but the powers it conferred were restricted. After the appointment of M. Doumer (1896), successor to M. Rousseau, this decree was again put in force on the former scale, and in 1898 it was supplemented by the decree of July 3 and 31, which definitely established the political and financial unity of Indo-China. The governor-general is the sole intermediary between the Indo-Chinese Union and the Home Government, the powers of which, with few restrictions, are delegated to him. He controls the civil services, and though prohibited from commanding in the field, disposes of the land and sea forces in the country. His diplomatic negotiations with foreign Powers must be carried on under the authorization and surveillance of the home authorities. The governor-general is assisted by the Superior Council of Indo-China, which meets monthly and is composed of the chiefs of staff of the General

Government, the deputy of Cochin-China, the presidents of the chief chambers of commerce and important native members. This council has as its chief task the drawing up of the general budget and of the local budgets. The Superior Council meets not only at Hanoi, the seat of the Government, but also at Saigon, Hué and Pnom-Penh. It delegates its powers to a "permanent commission" consisting of 13 of its members, and dispensing with the attendance of the local authorities of regions other than those in which the place of meeting is situated. The *contrôle financier*, which scrutinizes and sanctions all measures of the public services involving outlay of money, is dependent on the Ministry of the Colonies and returns communicated to the governor-general.

The governor-general is also assisted by a "council of defence," comprising the chief military and naval authorities.

Justice.—The whole of Indo-China is, in principle, subject to French justice, represented by a court of appeal and a certain number of tribunals. The decree of Aug. 8, 1898, established one court of appeal for French Indo-China: two chambers sitting at Saigon and the other two at Hanoi. Three tribunals of commerce are established at Saigon, Hanoi and Hai-Phong. There are nine courts of first instance, one at Pnom-Penh for Cambodia, and two at Hanoi and Hai-Phong for Tongking. These courts are supplemented by *juges de paix* in Cochin-China, and there are *juges de paix* at Nam-Dinh (Tongking) and Tourane; elsewhere in the protectorates the residents perform judicial functions. There are four criminal courts in Cochin-China, at Hanoi in Tongking and at Pnom-Penh in Cambodia. In Cochin-China Annamese law is administered in the French courts in suits between natives, but native tribunals have been superseded. In Annam-Tongking, outside the sphere of the French tribunals, the natives are subject to Annamese justice, represented in each province by a mandarin called the *An Sat* and in Cambodia the natives are subject to the native tribunals. At the same time, whenever a French subject or European or other foreigner is a party in an affair, French justice only is competent.

Public Works.—The order of Sept. 9, 1898, placed the public works of Indo-China under the "direct authority of the governor-general as regards works entered to the general budget account." There is a director of public works in Indo-China at Saigon, a director of engineering in the other countries. In 1895 a "special service" was created in Tongking to consider railway business.

Posts and Telegraphs.—The country is divided into two sections for the purposes of this service, the one comprising Annam, Tongking and Upper Laos, the other Cochin-China, Cambodia and Lower Laos.

Education and Culture.—The educational movement is parallel to the political, but as the province has over 2,000,000 children of school-going age much remains to be done. In 1924-25 primary and secondary French schools had an attendance of 2,525 (about half natives); the 3,395 Franco-native official schools, an attendance of 213,977; the private schools (native and missionary) one of 99,790, the expense of education being 6,000,000 piastres (1924). The 1917 public instruction code laid down the principle of the teaching of French, even in elementary schools, but there are reservations, defined in the *arrêté* of Sept. 18, 1924. The "University of Indo-China" at Hanoi, is a high school with many branches giving practical and theoretical training; it aims at turning out competent native assistants for the different French administrators, and training lawyers, planters, traders and manufacturers. Most of the students are Annamese. The *École Française d'Extrême Orient* at Hanoi, under the patronage of the *Institut de France*, conducts valuable research work in native art, history and language. It has a fine library and museums in Hanoi, Tourane, Saigon and Pnom-Penh, and has done epoch-making work in its *Inventaire* of Cambodian and Cham monuments, its excavation of the ruins of Angkor, etc. (See its two vols., *L'École Française d'Extrême Orient depuis son origine jusqu'à 1920* [1922] and its semi-annual *Bulletin*.)

Defences.—The divisional general commanding troops of Indo-China (Hanoi), has under him three brigadier-generals (Tongking two, Cochin-China). Troops consist of two regiments of

French Colonial Infantry (Tongking, Cochin-China); two battalions of the Foreign Legion; two regiments of artillery; two detachments of French gendarmes; two flying squadrons, which also do excellent work in mapping and fiscal service. There are four native regiments of tirailleurs in Tongking, one in Cochin China. There are five "military territories" on the Chinese frontier and in Laos. The medical service is relatively important

VIEW OF PNOM-PENH, CAMBODIA, SHOWING THE AUDIENCE HALL. PNOM-PENH, SITUATED ON THE MEKONG RIVER, IS THE CHIEF MARKET FOR THE PRODUCTS OF CAMBODIA, LAOS, UPPER BURMA AND PART OF SIAM

and helps in the general sanitary organization. The navy is under the command of a *capitaine de vaisseau* (Saigon). The local squadron has been reduced almost to nothing since the World War. There is a question of handing the Saigon arsenal over to a private enterprise.

Finance.—The unification of the budget brought about by M. Doumer (decree of July 31, 1898) specially contributed to that of the Government. The financial scheme is based on the political. In addition to the general budget, comprising the revenue and expenditure of the supreme Government, there are several local budgets, including the revenue and expenditure incidental to the individual provinces. The general budget, under 24,000,000 piastres in 1901, was 76,466,490 piastres in 1926. The Bank of Indo-China (capital £1,440,000), besides receiving deposits and discounting bills, has the privilege of issuing notes, a privilege renewed by the French parliament in 1925.

Commerce, Agriculture, Industry.—Although there is still a plethora of French officials (about 4,600), especially in the lower ranks of the Customs and Excise and similar services, there are over 3,000 French non-officials (males), traders, manufacturers and planters. In 1922 from 250,000,000-300,000,000 fr. were invested in private French enterprises. Rice remains the staple product; 4,750,000 ac. in the Mekong delta were under rice in 1920. There were 62,500 ac. of rubber plantations, and other tropical plants were cultivated successfully. The anthracite mines of Hongay and Dongtrieu produce 1,000,000 tons annually. The production of zinc (40,000 tons) and phosphates (20,000 tons) is important. In 1925, 33,833 hands were engaged in mining (329 Europeans). The presence of coal has given birth to a rapidly expanding industry in the Red river delta, where there are large cement works, brick, tile and ceramic works, three naval yards (besides the Saigon arsenal), two important French river steamer companies, three large cotton-spinning works and minor industries. Home industry (lace-making, etc.), employs many native women. The piastre, worth 2.50 fr. before the war, was, in 1926, worth 15 fr. (the piastre is worth 2,700 sapeks, the chief native coin, of zinc or tin); but on a piastre basis, exports have increased by 77% since 1900, imports by 14% only. Imports to France from Indo-China in 1925 were 612,000,000 fr., exports 760,000,000. Total exports reached 1,771,541,353 fr., of which 62% represented rice; imports reached 1,388,593,768 fr. The customs tariff is substantially the same as that of France, severe import duties

being levied on foreign goods. French goods pay no import duty, and goods exported thither are exempt from export duty, with the exception of sugar, which is regulated by special legislation, and of various other colonial products (e.g., coffee, cocoa, tea, vanilla, pepper), which pay half the duty applicable to similar foreign products according to the minimum tariff. Goods from French colonies pay no import duty. About 53% of the imports, comprising nearly all manufactured goods of European origin, come from France. China, Japan and Singapore are the other chief sources of imports.

Communications.—There are now 2,075 km. of railways. The general plan, formed in 1898, will include a great trans-Indo-China line, which will follow the coast from Hanoi to Saigon, and from which will branch the lines penetrating China, Laos, Cambodia and Siam. An important line, 126 km. long, is planned which will run from Tanap to Thakhek and link up Central Laos with Central Annam. Tourist traffic is now possible and encouraged. Over 20,000,000 piastres were spent during the years 1919-25 on dredging, irrigation, etc., and 50,000,000 piastres on the roads, of which there are now over 30,000 km. (11,000 metalled, 9,000 made possible for motors in the dry season).

BIBLIOGRAPHY.—I.—Official and semi-official publications: *Annuaire général de l'Indochine* (Hanoi annual); *Rapports au Conseil de Gouvernement* (annual); *Bulletin Economique de l'Indochine* (every two months with monthly statistical annexes); *L'Indochine* (no. spécial de la vie technique, industrielle, agricole et coloniale, 1922); *Bulletin de l'École Française d'Extrême-Orient* (bi-annual). Among the publications of the school must be noted: *Inventaire archéologique de l'Indochine*. (1) Monuments du Cambodge, 3 vol., with atlas by Lunet de la Jonquière (1902-12); (2) Monuments Chams de l'Annam, 2 vol. by H. Parmentier (*ibid.* 1909-18); *Bibliotheca indosinica*, by H. Cordier, 4 vol. (1912-15), an admirable bibliography of books and papers on the whole Indochinese Peninsula; *Mémoires du service géologique de l'Indochine* (Hanoi Imprimerie d'Extrême-Orient); *Revue indochinoise*, 1925, xxvii. year (*ibid.*); Henri Brenier, *Essai d'Atlas Statistique de l'Indochine Française* (Hanoi, 1914), 88 charts, 38 maps, with commentaries; *Service géographique de l'Indochine*, map scales: 1/1,000,000; 1/500,000; 1/100,000; 1/25,000 (deltas); *Bulletin des Amis de Vieux Hué* (articles of Annamese history, archaeology and art); J. de Galember, *Les Administrations et les services publics Indochinois* (Hanoi, 1924); Henri Lecomte, Membre de l'Institut, *Flore Générale de l'Indochine*; *Les Bois d'Indochine* (in preparation, 1926). II.—Non-official: Cl. Madrolle, *Guide de l'Indochine*, 2 vol. (new ed., 1924); H. Russier and H. Brenier, *L'Indochine Française* (Paris, 1911); C. B. Maybon and H. Russier, *Notions d'Annam* (Haiphong, 1916); Chassigneux, *L'irrigation dans le delta du Tonkin* (1912); C. Dussault, *Inventaire général de l'Indochine. Structure et géographie physique* (1927); Lt.-Colonel Abadie, *Les Races du Haut Tonkin* (1924); Henri Maître, *Les Jungles Moï* (1912); J. Commaile, *Guide aux ruines d'Angkor* (1912); Marquis de Barthélemy, *Mon Vieil Annam* (Recits de Chasse) (1925); Marcel Bernamose, *Les arts décoratifs au Tonkin* (1922); Paul Collard, *Cambodge et Cambodgiens* (1925); Georges Groslier, *Recherches sur les Cambodgiens* (1921); *Angkor* (1924).

HISTORY

French influence in Indo-China dates from as far back as the year 1787, when, through the efforts of a great French missionary, Pigneau de Behaine, bishop of Adran, a treaty was signed between the "king" (*Chua*) of Cochinchina, Nguyen phua Anh, and Louis XVI., king of France. Though the opposition of the then governor of Pondicherry, the count of Conway, and general events, such as the French Revolution, prevented the entire execution of the treaty, a number of French officers and men, conspicuous among whom were Colonels Olivier, Vannier, J. M. Dayot and J. B. Chaigneau, helped the Annamite prince to reconquer his throne, disputed by the Tay Son rebels, and to become, in 1801, the founder of the new imperial dynasty of the Nguyen. His line (under the name Gia Long) is still in possession of the power in Hué. The remains of the Vauban fortifications built by the French, who aided the Annamite prince a century and a half ago still confront the visitor to the capital and other towns.

Such was the respect Gia Long professed for the bishop of Adran that he had, at the latter's death in 1799, a tomb (temple) specially built for him, close to Saigon, and himself composed Pigneau's epitaph, which can be read to this day. Gia Long proved a great ruler; a new Code was enacted, inspired (as are most Annamite institutions) by the Chinese Code; great public works were undertaken, and a new land-survey instituted.

Anti-Europeanism.—His successors were averse to French influence and started persecutions of the Christian missionaries and natives. For 40 years, from 1833 onward, eight European bishops and 15 missionaries were put to death; 20 others incarcerated and tortured, and several died of misery in the mountains, where they had taken refuge. Many thousands of Annamese perished among the 60,000 who had then embraced the Christian religion (they are over a million now). The French and Spanish Governments (some of the priests killed were Spaniards) only intervened in 1858 by the capture of Tourane, the port of Hué, under Admiral Rigault de Genouilly; but the real campaign in Cochinchina began in 1861, under Admiral Charner. Saigon was taken in February, and by treaty of June 5, 1862, the three eastern provinces of Cochinchina were ceded to France.

French Suzerainty.—Then began the "administration of the Admirals" (1863-79), foremost among whom was Admiral de la Grandière (1863-68).

Under this administration the first protectorate treaty was signed with Cambodia, the local administration was organized, Doudart de Lagrée and Francis Garnier's exploration of the Mekong (1866-68) was undertaken, and as a counter-move to the continual revolts in the three western provinces of Cochinchina, these were annexed in 1867.

Admiral Dupré (1873), with Luro, an ex-officer of the navy, instituted at Saigon a college for French probationary administrators. In November of the same year, Lieut. Francis Garnier, with 188 men, became master of the delta provinces of Tongking (*q.v.*). He had been sent on a mission of enquiry into the differences between the merchant, Jean Dupuis, and the Annamese authorities in Hanoi. Garnier was killed in Dec. 1873. In March of the next year a protectorate treaty was signed by France and the emperor Tu-duc. Tu-duc, however, still sent an embassy to China promising "obedience," although he had promised "to conform his policy to that of France."

This raised many difficulties in the enforcement of the treaty. An expedition being deemed necessary, in 1882 Henri Rivière took charge, and was killed in 1883. Annam united with China in a war against France, in the course of which Admiral Courbet bombarded the Foochow arsenal and defeated the Chinese at Son-Tay. Hostilities ended with the signature of two treaties (with Annam June 6, 1884, and with China April 4, 1885). The frontiers between China and French Indo-China were defined in two conventions (June 26, 1887, and June 20, 1895), and the bay and territory of Kwang-Chao-wan, in the province of Kwangtung were leased to the French (April 12, 1898).

New Organization.—After the 1884 treaty a new French protectorate was organized, with Paul Bert as first résident-general. On Bert's death, M. Constans was appointed the first governor-general of Cochinchina, Cambodia, Annam and Tongking (1887). In the succeeding years lack of harmony between the French military and civil administrations and failure to appreciate the provisions of the protectorate system, led to difficulties. These were augmented by Chinese attacks along their frontier. Under the governorship of J. L. de Lanessan (1891-94) affairs improved and the decree of April 21, 1891, gave the governor-general real powers, which were clearly defined in the decree of Oct. 20, 1911, again reinforced by a decree on Sept. 11, 1920, whereby the governor-general became a legislator. He can dissolve or suspend the Colonial Council, an elected body mainly French, but his financial measures are supervised by the director of financial control. An ordinance of the governor-general can, however, at any time be revoked by the Colonial minister in France.

In Tongking, wherever the status of the Annamese is directly concerned, the sanction of the emperor is necessary. It was an ordinance of the emperor Khai Dinh (July 16, 1917), which ordered the putting into force, both in Tongking and in Annam, of the five new *Codes* on the organization of the tribunals, commercial and civil procedure and the penal laws. The new Civil Code was put aside for revision by a commission where Annamese mandarins are in the majority.

There was instituted in the colony a geographical service for explorations and surveys, and splendid geodetic and cartographic

work has been done. In 1927 M. Varenne prepared a new scheme, for the Council of Government to be composed of 60 members (35 Frenchmen and 25 natives), 32 of whom were to be elected by local assemblies, 12 (nine French and three natives) by the Chambers of Commerce and Agriculture, and 16 (ten French and six natives) to be appointed by the governor-general.

In Aug. 1928 Pierre Pasquier was appointed governor-general. His whole administrative career has been in connection with Indo-China, the first to enter on his task with such a preparation. There are many problems still confronting administrators in a country of 20,000,000 inhabitants of mixed race and civilization. The old self-recruited village oligarchy of headmen is dying out; attempts to combine in some measure the old and the new regime have not been conspicuously successful. So far compulsory education exists only in Cochinchina, and the general medium of instruction is *quoc ngu*, or romanized Annamese, a system devised originally by the Portuguese to avoid the use of Chinese characters.

The present emperor of Tongking, Prince Vinh Tuy, whose official name is *Bao Dai*, succeeded his father in 1926. While he is being educated in France, according to his father's wish, the regency is exercised by the president of the council of Annamese Ministers. (See also CAMBODIA, TONGKING, SIAM, ANNAM, subsections *History*.) (Hl. Br.)

INDO-EUROPEANS. The term Indo-European appears to have been invented by the well-known physician and physicist Thomas Young. In an article in the 10th volume of the *Quarterly Review* (Oct. 1813) he uses the word without any remark as to its being a new coinage. The word was devised especially to indicate a family of languages, but from the beginning it has been found very difficult to keep apart the use of the word as indicating languages and the application of the term not only to the speakers of the languages at any given period but also to the supposed original speakers of these languages. The effect of this confusion has often been serious. It is obvious that a language may be spoken by persons who have no blood relationship with the general body of speakers of the language, and that this body itself may not be all of one and the same origin. Thus the negro in Liberia or in the Southern States of America who speaks English as his mother tongue may have no drop of English blood in his veins, and even 200 years ago Daniel Defoe was certain that there was no such person as the "true-born Englishman."

Ever since it was possible to identify a separate family of languages as Indo-European, continual efforts have been made to ascertain who were the original speakers of the language from which the surviving members of the family, or those which are recorded in literature or other monuments, have sprung, where was their home, what were their surroundings and their manner of life. The first of the elaborate statements of these problems was that published by Adolphe Pictet in 1859. The more important attempts of the same kind which have appeared since are enumerated in the bibliography at the end of this article. It is hardly necessary to say that the majority of such attempts deal mainly or altogether with the evidence derived from language. This is necessarily so, because, when the question arose, the linguistic scholars were the first who were ready to carry on the investigation; but the problem can be attacked in various other ways, and it is only by an attack converging from all quarters that a certain result will ever be attained.

Fauna.—From language it is clear what were the animals, what were the plants and what were the seasons in the country whence this language was derived. The animals still familiar amongst us were well known; the sheep, the cow, the horse, the dog and the pig. The names of the goat vary much more from language to language; but it does not necessarily follow from this that the goat was not known until a later time. Animals for which there are no early terms in the Indo-European languages are the lion, the tiger, the elephant, the camel and the ass. It may therefore be safely concluded that these animals did not exist in the original habitat. The lion, at one time, certainly roamed over a much larger area than it does now. According to Herodotus lions were found as far to the west as Macedonia and the prevalence of the

representation of the lion in monuments of Asia Minor and Persia is proof to some extent, that the animal was well known. It still survives in Cutch but has lost its mane and is on the way to extinction in Asia. As there is no word for the elephant and no representation of it in the more western part of Asia or in Europe it is clear that this animal also was unknown. The same is true of the tiger and the camel and the ass. In Asia the common beast of burden was the ass. The horse, though known in Mesopotamia from the time of Hammurabi before 2000 B.C., owes its introduction to the Kassite invasion of 1926 B.C., and was called the mountain ass. Palaeolithic man was able to represent in his drawings two species or varieties of horse. The name of the cow has the same origin in almost all the languages and the same is true of the sheep, the pig, the dog and the mouse; but in their wild state the same environment is not suitable to all. The horse is an animal of the prairie; it lives in the open plain and the foal is able from the day of its birth to accompany the mare. The cow, on the other hand, in the wild state lives in countries with open spaces well provided with woods or clumps of trees. When the cow travels afield to find food, the calf is unable to accompany her and has to be hidden in some brake or thicket, as it can walk but feebly and its eyesight is still imperfect. Unless it were so hidden it would fall a prey to animals like wolves or eagles, both of which seem to have been known to the first Indo-Europeans. The grass which suits horses or cows is unsuitable for sheep which prefer the short crisp grass of upland pasture. If, therefore, all these animals were well known to the early Indo-Europeans they must have lived in an area where the landscape was diversified. The country seems to have no connection with the sea; the more widely spread meanings of the word for the sea are either moor or marsh. That open water was known is shown by the fact that there were words for water birds, the swan, the goose and probably the duck, but all of these could find a resting place in very small sheets of water. From what has been said, it will be clear that the Indo-Europeans must originally have lived in the temperate zone. The bear was known, but which species we cannot tell. It is well known that the name "bruin" meant the brown bear, being cognate with the Lithuanian word *bėras*, for the Lithuanian word is used as an adjective meaning brown. Other animals known were the beaver and the hare, the word for the beaver being generally a reduplicated form from the same stem as the word for the bear and the hare, meaning originally the grey beast. Its origin was the same as that of the Latin adjective *canus* from an older *cas-nos*.

Flora.—The trees and other plants are not so easy to identify because it is found that when men migrate to a new area, they carry with them the names of plants and, to some extent, also of animals and apply them to plants or animals in the new area which bear some resemblance to the plants or animals they have left behind. Thus in England the oriental plane, so well known in Asia Minor and Persia as the Chinara, grows only with difficulty north of the Trent and in northern Scotland not at all. But the name plane is preserved, notwithstanding, and applied to the sycamore which resembles the plane in being an umbrageous tree and having a leaf somewhat similar. In the same way, the English in America have given the name of robin to a much larger bird, because it has a red breast. The trees most widely spread in the temperate zone are the willow and the birch. The birch extends from the British Isles to the farthest Himalayas. Some variety of willow is the first tree to grow near streams in a country like Siberia which has not long been freed from surface ice. On the other hand, some of the commoner trees, like the beech, do not penetrate far into the southern peninsulas of Europe. The consequence is that in Greece the word corresponding to *beech* in English and to *fagus* in Latin, means oak or sometimes possibly chestnut. In the same way in Latin the word cognate with the English birch is used for the ash, *fraxinus*. The pine in some of its numerous forms was also certainly known.

Cereals and Seasons.—More important, perhaps, for the history of the race, is the existence of cereals. Within historical times, only two new cereals have been introduced into Europe, rice and maize, though a plant of another kind, buckwheat, was

brought in by the Tatars and has received its name because its fruit was ground, and treated as a cereal. Many attempts have been made to connect the Greek *oryza* with the Sanskrit *vrihi*, which in modern Persian appears as *birinj*. But traffic down the Red Sea was mostly with southern India and the simpler explanation is to connect the Greek word with the Tamil, *arishi*. The early names for grain are very ambiguous. The word *corn* connotes in England wheat, in Scotland oats, in Sweden barley, in Germany rye and in America maize. The most widely spread name for a cereal is that which appears in Sanskrit as *yava*, in Greek as *zéa* or *zéid*, the latter a derivative of the former, in Lithuanian *jawā*. It may have meant originally barley, but is also used for spelt, a simple and ancient form of wheat, which, as being such, was long used in religious ritual.

The names for the seasons of the year help us somewhat. There are words widely spread for winter and for snow. The stem *hima* is found in the name of the Himalayas ("the abode of Snow") and in the Greek *kheima* with its adjective *duskhimos*, the Latin *hiems* and many others. We do not use a word from its root for winter ourselves; but notwithstanding we have a word borrowed from the Norse and much used by Cumberland shepherds, *gimmer*, a winterling or sheep one year old. There is less agreement about the other seasons but there is a fairly widely spread word for spring. In many countries summer is simply the hot season. For harvest the languages do not agree very well; the Latin *autumnus* is simply the "season of increase," which we have introduced into English as *autumn*. The word *harvest* is probably the season of fruit gathering, not of corn harvest, the two being still distinguished in German as *herbst*, the fruit harvest, and *ernte*, the reaping time. Snow was certainly known because the stem is found in so many languages, but with lofty mountains in the neighbourhood that might well be, even in a hot climate; from the names of the animals and plants, however, as we have seen, the climate was temperate and if it was a continental climate as, from the absence of words for sea, it apparently was, the climate might be severe, even if it were tolerably far south. The areas that will satisfy the conditions require a land with a temperate climate, remote from the sea and shut off from other areas, for otherwise it seems impossible that languages with so complicated a grammatical system as the Indo-European could have developed, bearing so close a resemblance to one another and on the whole so strongly differentiated from other languages. The only area which will satisfy the conditions postulated by the languages is the great area in Europe which includes practically the former empire of Austria-Hungary. In this area are found rich corn land, great prairies for the production of horses, pasture for cattle in the plains and for sheep on the mountain slopes, while the mountains themselves contain a large supply of minerals which were later utilised by man. But when the migrations from this centre began, the use of metals had not advanced very far, the only word for metal common to many languages being that which appears in Sanskrit as *ayas*, in Latin as *aes* and in English as *ore*. The word at the time of the migration meant either copper or bronze which sometimes, as in Greek, are not distinguished, the first bronze probably being a natural alloy. From what has been said it is clear that much could be done on this subject by the geographers.

Migration.—Even when we have found a people using a certain vocabulary, it is necessary to discover, if they migrated from their original habitat, in what manner it was possible or probable that they did migrate. It is, for example, a common belief that migration from Europe to Asia or the reverse, was carried on largely by the steppes of Southern Russia, the shores of the Caspian and Turkistan. In ancient times, however, progress in this direction would not have been so easy as it is to-day. In the Caspian area very large and important changes in the earth's surface have taken place. The eastern end of the Caucasus, for example, has sunk till it is now far below the level of the Caspian. The northern Caspian is steadily being filled up by silt from the Volga. In earlier times, it extended much further north than it does at present, while eastwards its extent was very much greater, including within its area not only the present Sea of Aral and

what is now the intervening desert, but also passing still further to the east to a distance which is not yet clearly determined. Scholars often talk lightly also of great hordes passing the Caucasus. This also would be very difficult to achieve. According to early Greek notions the Caucasus was a barrier without openings through it and in fact at the present day there is but one, the Pass of Dariel. Historical migrations, in fact, have taken place much more readily across Asia Minor than across the Steppes. The main movement from Asia into Europe which went north of the Caucasus was in early times that of the Scythians and in mediaeval times that of the Hungarians. That the migration of the Indo-Europeans was through Asia Minor is proved by the discovery in 1906-07 of a large mass of records dating from the 15th and 14th centuries B.C., at Boghaz Keui, an important site east of the river Halys. Here were discovered the archives of the ancient Hittite empire, recorded in eight languages of which two have a certain Indo-European element in them. The most important is called Kanisian by Dr. Emil Forrer, who has been very successful in their decipherment. The grammar of this language, its noun and verb forms, are clearly Indo-European; but only a small part of its vocabulary is so, the main part coming from an unknown tongue. The first records of this language which were discovered came not from this find at Boghaz Keui, but from two letters discovered many years before, in the archives of Ikhnaton (*q.v.*), the heretic king of Egypt at Tell-el-Amarna. The mixture of two languages might be compared to what has happened in English where the pronouns, the numerals and the few remaining inflections of noun and verb are Teutonic but the bulk of the vocabulary is of Latin, or of Greek origin. The forms of this language, particularly in the names of certain deities, and of the numerals were so like those of Sanskrit that the first investigators were of opinion that either the records proceeded from Indians advancing westwards, or that the original home of the Indo-Europeans must once more be carried back to central Asia, where it had been located by some of the early authorities. A difficulty was found in the fact that the existing remains of the ancient languages of Persia—Zend and old Persian—as represented in the dialects of the Avesta and the kindred tongue of Darius' inscriptions at Behistun were so much less archaic in sounds than either the forms of these records or of Sanskrit. The explanation, however, is simple. When the speakers of Sanskrit passed over the mountains into a new country, they found themselves faced by powerful tribes more numerous than themselves and speedily realized that if they were not to be absorbed, they must stand aloof from mixture with the native tribes. Hence the beginning of the system of caste in India, for the Sanskrit word for "caste" means colour. The changes found in the language left behind in Persia must have taken place after the migration of the emigrants to India. This is not at all unusual. In the 16th century important changes took place in Spanish, but these changes were not shared by those who had already established Spanish in America. The English settlers of New England carried with them the forms *noos* for *news* and *Toosday* for *Tuesday*, because the *y* sound before *u* had not developed when these settlers left England.

If the original home of the Indo-Europeans is really located in Austria-Hungary, we should expect a considerable number of the Indo-Europeans to have been pile-dwellers. For this country had at one time much more water in it than it has now, when the Platten See, a shallow marshy lake, is all that remains of what was at one time a vast expanse of slowly drying morass. That there were amongst them many pile-dwellers, we can be certain, because they carried into Switzerland and into Italy for the western migrations, the same form of habitation, and gradually extended it further to the West.

Anthropology.—What manner of men were these emigrants? In Germany many scholars contend that they were tall men with fair hair and blue eyes and they attribute to the Indo-Europeans all the characteristics of the ideal German. For this, however, there is no solid foundation. It is said by these scholars that when Homer talks of *xanthos Menelaos*, this should be translated "yellow haired Menelaos." This translation, however, is not accurate. To a Greek *xanthos* did not mean blond, but brown,

as is clearly shown from the use of the verb, which signifies "to change the colour of meat in roasting," so that the colour would not have been lighter than auburn. In fact, when the Greeks came in contact with German children they did not know how to describe the colour of their hair and said they had hair like old men and described them as *polioi*, "with grey hair."

The anthropologists at one time maintained that the Indo-Europeans had long heads as distinct from other people with short heads. The mixture, however, of long and short heads is not a new thing. As Sir Arthur Keith points out (*Antiquity of Man*, vol. i. p. 110 [1925]), the antiquary, Dr. R. R. Schmidt, found at Ofnet, fifty miles south-west of Nuremberg, a large number of skulls of the Azilian epoch (a period linking up palaeolithic with neolithic times), some of which were long and others short. There is no reason to suppose that the Indo-Europeans had only one type of skull. No records lead us to suppose that we can trace the Indo-Europeans back more than ten thousand years. In earlier Europe there were peoples of different types, some of a physical frame now confined to the natives of South Africa, others with features akin to those of native Australians, and others again of types which no longer exist. The Basque language in the Pyrenees is a last relic of languages which preceded the Indo-European in the west of Europe; and the characteristics of colouring, hair and eyes of natives of western Britain and western Ireland, which Huxley called Iberian, are probably the relics of this population which has been almost absorbed. In Persia, on the other hand, a short, very dark people (*negrito*), which survives only in the extreme south-west of Asia, apparently preceded the Indo-European stock. The value of the relation of length to breadth of head, to which the elder Retzius first referred, has been much exaggerated, for the total content must be of more importance than the relation of length to breadth. As has been emphasized in recent years by Mr. Griffith Taylor, the height of the brainpan is worthy of consideration.

Pottery.—Still more recently the subject has been attacked from another point of view. In 1902 Professor Kossinna of Berlin undertook to show that pottery would be a more certain index to the history of peoples than any of the other methods proposed. But in the quarter of a century which has since elapsed, Professor Kossinna has withdrawn almost all the statements which he then made and his proposed new treatment of the Indo-Europeans has stuck fast after one part was published. That, however, evidence will be forthcoming from this side is certain. But a good deal more has still to be done in identifying the makers of particular types of pottery before this clue can be regarded as of more value than any of the others. At present the best chance of progress lies in the possibility of dating positively, and linking up with the linguistic evidence, the results which can be derived from the "Bell-beaker Civilization" and the Megalithic graves which extend very nearly over the same area which was covered by the early migrations of the Indo-Europeans. The probability is that the Indo-Europeans and their civilization arose from the mixture of two earlier types, a Mediterranean and a Northern type. But Schuchhardt in the second edition of his *Alteuropa* (1926) goes further and boldly assigns (p. 282) the Indo-Europeans to a mixture of the Germans coming from the north and the Celts from the Danube area, a stock in Thüringen possibly first "indogermanizing" north Germany by settlement and south Germany by conquest. To this he has added (*Sitzungsberichte der preussischen Akademie*, Feb. 16, 1928) that it was the conquest by the Thüringians of South Germany and Switzerland that created the Celtic stock; the Thüringians afterwards wandered to the Danube and were thus the original stock of the Indo-European people.

Language Classification.—Leaving these archaeological points to be definitely decided by future investigation, we may classify the Indo-European languages according to their connections. The Indo-European languages fall into two groups distinguished from one another by their treatment of certain guttural sounds. In one group, lying mainly in Europe, these sounds remain as *k*, *g*, *kh* and *gh*, whereas in the other group they change into some form of sibilant *ç*, *z* and the aspirated sounds either drop the aspiration and are treated as *k* or *g*, or appear as *h*. The causes

for this distinction are not certainly known and the distinction did not mark a deep difference between the languages at an earlier period, because the Greek, which is a *k* language, resembles in its syntax Sanskrit, which is a *ç* language, more than any other. The two series are generally named from the word for 100, in Latin *centum* (*kentum*), in Zend *satem*. The languages which preserve the guttural are *centum* languages, those which change it into a sibilant are *satem* languages. Thus the Greek *kuōn* "dog," Latin *canis*, appears in Sanskrit as *çvā* (*n*) and in Lithuanian as *szuō*. The chief *centum* languages are (1) Greek, in three distinct groups of dialects, Aeolic, Ionic and Doric, with more archaic forms in Arcadian and Cyprian. (2) Latin and the other Italic languages of Italy, Oscan in Campania and the South, Umbrian on the East of the Apennines. (3) The Celtic languages, which fall into two groups according to their treatment of an original combination of a guttural with a *w* sound like the English *qu*. One group changes *qu* into *p* (ancient Gaulish, Welsh, Cornish, Breton), the other represents *qu* by *c* (Irish and its descendants, Scotch Gaelic and Manx of the Isle of Man). Thus, corresponding to Latin *quis* is Irish *cia* and Welsh *prwy*. (4) The Teutonic or Germanic languages which fall into three groups: (a) Gothic, (b) Norse (Danish, Norwegian, Icelandic, Swedish); (c) West Germanic, including English, Frisian, Dutch and Flemish, Low and High German. The most distinctive feature of this group is the "sound shifting" which the stop consonants and *s* have undergone, and which are catalogued under the action of "Grimm's Law" and "Verner's Law," in the treatment of Teutonic languages. (5) Very remote from these four sections which are all in Europe, is Tocharish, presumably the language of migrants from somewhere much farther to the west, though the records of this now extinct language are found in Chinese Turkestan. (6) The Indo-European section of the Hittite languages (*see above*).

The *satem* languages are (1) in northern India Sanskrit and its descendants, and in Persia and its adjacent countries the ancient dialects called Iranian, viz., Zend (of the Avesta), Old Persian, Sogdian and North Iranian; Sanskrit and Iranian together form the Aryan branch properly so-called, though in England the word has often been applied wrongly to mean Indo-European. (2) Armenian, (3) Slavonic in its numerous dialects and Baltic (Lithuanian, Lettish, and Old Prussian, which is now extinct), (4) Albanian, more probably the descendant of the Ancient Thracian than of the Ancient Illyrian which occupied in part the same area. The relation of Illyrian to the Ancient Venetic, once spoken north of the Po and to the Ancient Messapian spoken in the heel of Italy, is not yet definitely ascertained. The other important language of Italy, Etruscan, did not belong to this family, but seems to have been related to Ancient Lydian and other languages of the Levant now extinct. (*See also articles on HITTITES; ARYANS; MIGRATIONS*, and separate articles on various languages.)

Brugmann, *Grundriss der vergleichenden Grammatik der indogermanischen Sprachen* (2nd ed., 1897-1916), of which a small additional part has been published since the author's death in 1919; a shorter work by the same author is *Kurze vergleichende Grammatik* (in 3 parts, 1902-04), dealing only with the more important languages; H. Hirt, *Indogermanische Grammatik* (the first four vols., only, are published, 1921-28); A. Meillet, *Introduction à l'étude comparative des langues Indo-Européennes* (1903, now in the 5th ed.), and *Les dialectes indo-européens* (1908). The comparative grammar of Latin and Greek is often treated separately, as by A. Meillet et J. Vendryes, *Traité de grammaire comparée des langues classiques* (1924); P. Giles, *A Manual of Comparative Philology for Classical Students* (3rd ed. in preparation). A complete bibliography of recent publications appears annually in the *Indogermanisches Jahrbuch* begun by A. Thumb and W. Streitberg in 1913. (P. Gr.)

INDOLE (BENZOPYRROLE), first prepared by A. Baeyer in 1866 and regarded by him as the parent substance of indigo. It crystallizes in colourless lustrous leaflets, melts at 52°C , boils at $253\text{--}254^{\circ}\text{C}$, is readily volatile in steam and easily soluble in water, alcohol, ether or benzene. Its odour is generally faecal, but after careful purification and in sufficient dilution indole possesses a not unpleasant odour of flowers. Accordingly it finds a limited application in perfumery. Indole occurs in the coal-tar fraction (see COAL TAR), boiling at $220\text{--}260^{\circ}\text{C}$; after removal of phenols and strong bases the oil is treated with sodium or sodamide to form sodium indole, which is separated mechanically and decomposed by water. It is synthesized by boiling dichloroether, $\text{CH}_2\text{Cl}\cdot\text{CH}\cdot\text{Cl}\cdot\text{OC}_2\text{H}_5$, with aniline and water, or by heating ethylaniline to redness. These reactions indicate its constitution (I.).

Scatole (3-methylindole; II.) occurs in human faeces, of which it is the chief volatile constituent; it melts at 95°C and boils at $265\text{--}6^{\circ}\text{C}$.

INDONESIA, a term used to indicate the group of islands variously known as the East Indian archipelago, the East Indies and Philippine islands, etc. In Ethnologic usage the term relates to a family speaking languages of a well defined type, and having physical characteristics which are easily recognizable. (See Ethnology.) Geographically the term Indonesia comprises eight insular areas: (1) Madagascar, (2) the Sumatra group, (3) the northern part of the Malacca peninsula, (4) Java, Madura and Bali, (5) Celebes, (6) Borneo, (7) the Philippines and (8) the islands east of long. 120°E . The basis of the classification is mainly linguistic, and the Indonesian language family has supplied many of the links between Polynesian, Melanesian and Micronesian speech-systems. For the geography, etc., of Indonesia, see the articles under headings 1-7 above and PACIFIC ISLANDS.

For anthropology see ASIA; *Anthropology and Ethnology*, § Farther Asia. (X.)

ARCHAEOLOGY

In Indonesia there have been found remnants of human types and cultures still represented in Australia and the Pacific.

The skull fragments found by Earl in a shell-mound in the Province of Wellesley on the west coast of the Malay Peninsula were described by Huxley as Australoidic. Skulls of Melanesian type were excavated in the caverns of Tongking by Mansuy and his collaborators. The skulls and fragmentary skeletons of a man and a woman, discovered by Van Riedschoten and Dubois in 1889 and 1890 in a mountain slope above Lake Rawa Bening near Wadjak in eastern Java, belong to a dolichocephalic tall race thoroughly different from the present inhabitants of Java and resemble the skulls of recent Australians. Dubois therefore terms the Wadjak men "Proto-Australians."

PALAEOLITHIC PERIOD

The term palaeolithic is not used here as indicating that the palaeolithic civilizations of south-eastern Asia are of the same age as those of Europe. All the palaeolithic finds as yet known from Indonesia belong to the geological present.

The Palaeolithic Culture in Celebes and Sumatra.—The Lamontjong caves are situated in the interior of the south-western peninsula of Celebes, about 60km. east of Makassar in the territories of the Toala, a tribe now tilling the soil, though they probably lived till recently by hunting and collection of natural products. The caves were discovered and examined in 1902 and 1903 by Paul and Fritz Sarasin. In five of them the ash stratum forming the ground contained remnants of game animals, implements of stone, bone, teeth and shells. The stone implements (mostly of quartzite, andesite, limestone, only exceptionally flint) betray a very crude manufacture. The whole stone lump was caused to burst with a blow after which the few suitably splintered

flakes were selected for further fashioning and the rest were thrown away. Among the implements were scrapers, points and two-edged, more seldom one-edged knives. Especially numerous were stone arrow-heads, partly with dented edges, partly barbed. Dented stone flakes of scale-like shape were probably inserted into wooden clubs like those now used by the Toala with metal flakes. Spindle or prick-shaped arrow-heads of bone or the teeth of the wild boar were probably used, the one end serving for a point, the other one for a barb as in the South Seas and America. Small whistles were manufactured of long and phalangeal bones; pieces of shells were used as scrapers and scratchers. Perforated fragments of human bones were probably worn as amulets. Remains of domestic animals and cultivated plants are completely absent. The dog perhaps was known. All the animal species remains of which have been found in the caves still live in Celebes.

Most of the stone implements of Lamontjong at first sight resemble those of late European palaeolithic times, especially the Magdalenian, but were manufactured in a far more primitive way. The barbed arrow-heads, however, show a form which, in other parts of the globe, only occurs in neolithic times. The culture of the cave-dwellers of Lamontjong was probably influenced by some neighbouring neolithic civilization. A fragment of an earthen pot was found in the ash layer. The occurrence of stone arrow-heads in the caves is also remarkable since the bow is almost unknown at present in Celebes, and with this sole exception stone arrow-heads are not found among the prehistoric finds of Indonesia and Indo-China. Since barbed arrow-heads are frequent in the neolithic period of Japan, and arrow-heads of stone are said to have been used in the Philippine islands as late as the 17th century, these implements may be regarded as remnants of an ancient cultural current that in the neolithic period may have come from Japan through the Philippines as far as Celebes. In any case this contact must have been but slight. The culture of Lamontjong is therefore a culture of hunters and collectors of natural produce with a palaeolithic base and a slight neolithic touch. The stone implements were immediately covered by a very recent layer with iron implements and fragments of china. The present Toala may be considered the direct descendants of the stone-age cave-dwellers.

In the cave of Ulu Tjanko in the basin of the River Djambi, in central Sumatra, Dr. Tobler found a palaeolithic dwelling containing remnants of food and skeletal fragments, apparently of a slender-framed race, a number of implements manufactured of obsidian, especially knives and points of different size, and some scrapers. Typologically this Sumatra palaeolithic culture is connected with that of the Toala caves of Celebes, yet differs from it by the diverse material, the better working of the stone, the lack of the barbed and dented arrow-heads and of any perceptible neolithic influence. In both cases we have "point and blade civilizations" with rather small implements, which cannot, however, be called microliths. They are radically different from the coup-de-poing culture of India, in spite of local differences, but are probably related to the stone-age culture of Ceylon and that discovered by Nötling and Swinhoe at Yenangyaung in Upper Burma. This late palaeolithic point and blade culture must have been once widely spread over broad areas in southern Asia, possibly propagated by the small and cymotrichous race now surviving in small, scattered remnants like the Vedda, Sakai, Toala, etc.

The Coup-de-Poing Culture of Sumatra.—A culture of different character has lately been discovered by Dr. van Stein Callenfels in the country around Medan and Deli in the eastern division of north Sumatra. It is characterized by crude implements of almond-like, elliptical or pointed-oblong shape. These coups-de-poing and pick-axes are mostly manufactured by working a stone nodule with blows on only one side, the other side showing the natural unworked surface. On account of its frequency in Sumatra Dr. van Stein Callenfels termed this type which also occurs on the Indo-Chinese mainland, the Sumatra type. Traces of this civilization were found along the river courses of eastern Sumatra. In a shell mound in the neighbourhood of Medan examined in 1925-26, the stratum containing the

coups-de-poing was immediately covered by another one containing iron weapons of types identical with those still used to-day in northern Sumatra though somewhat old-fashioned. This north Sumatra coup-de-poing palaeolithic culture which began at the latest about 5000 B.C. lasted up to a late time, and was succeeded by a culture already acquainted with iron. This Sumatra culture is closely related to that from the oldest cave strata of the Malay Peninsula and Tongking, where the palaeoliths and coups-de-poing worked exclusively on one side are found in great number, but together with so-called protoneoliths, roughly worked or even unworked stone axes with ground edges. Since these protoneoliths are missing in Sumatra, Stein Callenfels regards this Sumatra culture as an earlier stage of the continental one, brought to Sumatra by a tribal and cultural wave still ignorant of stone-grinding. These coup-de-poing cultures of Sumatra and Indo-China belong probably to a great group of related late palaeolithic and mesolithic cultures once widely spread over large parts of the globe.

The "Horn and Bone Civilization" of Java.—A third, apparently preneolithic civilization of Indonesia was discovered in 1926 by Engineer van Es near Sampung, Residency of Madiun, Java, in a cave on the slope of Volcano Lawu. The very thick layer contained two skeletons of a tall-grown race (1.70m. to 1.80m.) interred as lying squatters, numerous implements of horn and bone (arrow-heads, fishing-hooks, etc.), grinding stones that had served for grinding ruddle, thousands of unworked fragments of silex, jasper and agate, but no worked stone implement.

THE NEOLITHIC PERIOD

The number of neolithic objects in the museums is very large, almost exclusively stone axes found by chance. About pottery, as yet practically nothing is known. Most of the megalithic monuments undoubtedly belong to the metal periods. The neolithic cultures of Indonesia may be divided by local criteria.

Eastern Indonesia and the Philippine Islands.—The neolithic period of eastern Indonesia (Celebes, Moluccas, Little Sunda islands, South-west and South-east islands) is characterized by two types of stone axes (a) somewhat clumsy broad-necked axes having the shape of a short rectangle or trapezium, often approaching the quadrate and square in the transverse section; (b) narrow or pointed-neck axes with lenticular or oval transverse section. The second type is very frequent in ancient Europe; is characteristic of the neolithic period of India, occurs, though seldom, in Japan, and is still present in New Guinea and Melanesia, directly derived from the ancient forms of east Indonesia. It is not known how this type came into Eastern Indonesia as, except there and in Borneo, it is not known in Indonesia or further India. It may be due to influences from India, or, with the stone arrow-heads of the Toala caves, to a cultural current from Japan. The occurrence of ancient stone hooks reminiscent of the magatama of the Japanese neolithic period possessed by some Dayaks in Borneo might thus be explained. As is shown by the shouldered celts found in Formosa the neolithic culture of this island must at some time have been in close connection with that of Indo-China. The existence of stone axes is however proved with certainty at least for Mindanao and the Visayas. Two such axes from a cave on the Island of Masbate have been published with illustrations. Of oblong-rectangular shape they resemble certain Indo-Chinese stone-axes more than those from Indonesia. In the same place numerous pottery fragments decorated with scratched waving lines and points were found. It is, however, impossible to say with certainty, whether they were coeval with the stone implements.

Western Indonesia.—The oldest neolithic type of western Indonesia, especially of Java, according to Stein Callenfels seems to be a broad-necked axe the two broad sides of which have a swell whereas the narrow sides frequently do not show a single plane but several narrow ones joining at greater or smaller angles. This axe is about as thick as it is broad. Java has furnished by far most of the neolithic material, due partly to her dense population and very extensive agriculture as the occasions for finds are thus multiplied. The neolithic civilization there seems to

have reached a very high level, as shown by the beauty and perfect working of the implements of the late neolithic period, which are frequently made of precious stones: jasper, chalcedony, lydite, opal, agate. Especially characteristic of Java are thin flat-axes of oblong trapezium-shape, mostly with distinct side-planes and frequently with chisel-like edge of one-sided bevel. Frequently one side is convex, the other concave so as to make the whole head longitudinally crooked. All these types which also occur in Sumatra, show a certain resemblance to those of the Malay Peninsula and of Upper Laos. It thus seems that in late neolithic times a cultural and perhaps also tribal wave spread from the region of Luang Prabang on the Mekong southwards over Siam and the Malay Peninsula as far as Java. Besides these flat-axes and adzes, gouges also occur in Java. The most characteristic type, however, probably found exclusively in Western Indonesia, are the pick-axes. On their upper side either they have a swell or show two planes sloping like a roof from a middle ridge. The transverse section may be semi-circular, triangular or pentangular according as they have side-planes or not. The upper side is frequently convex, the under side sometimes concave, thus making the axe head longitudinally crooked. The edge always forms a point. On the under side it is frequently ground hollow. Such pick-axes are also known from Bali and the southern half of Sumatra.

Neolithic Cultural Provinces and Chronology.—In the Malay Peninsula another kind of pick-axe occurs the upper side of which is for the most part flat and is ground to a point only in front. The under side is always flat and sometimes ground hollow at the edge. Since the neolithic civilization of the Malay Peninsula is in other respects very closely related to that of Upper Laos (region of Luang Prabang), it represents perhaps a transition or a mixture of the stone-age civilization of Indo-China and Western Indonesia. The south of the Malay Peninsula is distinctly opposed to the remaining part of Indo-China by the lack of shouldered celts and by the occurrence of the pick-axes mentioned. Thus the south of the peninsula belongs rather to Indonesia than to Indo-China.

The division between the territories of the neolithic axe-types of Eastern and Western Indonesia, seems to correspond with the division between the East and West Indonesian languages and represents to-day the limit of distribution of many important cultural elements. In Borneo Eastern as well as Western Indonesian axe-types (also pick-axes) are found side by side, and the Dayak languages are intermediate between those of Eastern and Western Indonesia. Thus the present distribution of tribes and languages in Indonesia goes in substance back to the neolithic period, at least therefore to the first millennium B.C.

More accurate criteria for the chronology of the Indonesian neolithic period are derived from the distribution of the Indo-Chinese shouldered celts. The distribution of these celts closely agrees with that of the Austro-Asiatic languages and from that it is to be inferred that they belonged to the cultural inventory of the ancient Austro-Asiatics (Mon-Khmer). They are found in Indo-China (except the south of the Malay Peninsula) in Assam, Orissa, Chota Nagpur, in the Santal Parganas and near Allahabad, in regions of India in which Mon-Khmer or Munda (Austro-Asiatic) languages are either spoken to-day or once were spoken. There was probably a tribal migration starting from Indo-China, hardly later than between 1500 to 1000 B.C. Since the shouldered celt is missing in Indonesia and the south of the Malay Peninsula, we may infer that the separation of the Austronesians (Malayo-Polynesians) from the Austro-Asiatics (Mon-Khmer) and also their migration to Indonesia took place at a time when the shouldered celt had not yet been developed, that is about from 2000 to 1500 B.C., though it may have happened earlier. Since the late phases of the Indonesian neolithic period are ascribable to these migrations, we must suppose a considerably greater age for the earlier phases.

The stone-age appears to have terminated at very different times in the different parts of Indonesia. In Western Indonesia (Java, Sumatra) the foundation of Indian expansion and rule commenced at the latest in the second century A.D., perhaps

earlier. Yet it is almost certain that mining and the manufacture of iron were known there before the arrival of the Hindus. Traces of a bronze age spread to the remotest east of the archipelago, and are especially numerous in Sumatra, Java, Celebes and Sumba. Therefore it is probable that in some parts of Indonesia the neolithic period had terminated in pre-Christian times. In other parts, however, it appears to have lasted much longer. The working of metals has not yet been fully established in every part of Indonesia, and the use of implements of stone, bone, wood and bamboo still survives.

INDONESIAN AND FURTHER INDIAN ART. To a certain extent, and in a broad historical survey, all of Further India or Indo-China (Burma, Siam, Malay peninsula, Cambodia, Campā and Indonesia [Sumatra, Java, and Bali]) may be treated as a unit. Throughout this area the population consists essentially of Sino-Tibetan races who have occupied the river valleys (Irawadi, Salween, Menam, Mekong) and islands by successive migrations from prehistoric times to the 14th century; throughout this area Indian cultural influences began to be felt before or about the beginning of the Christian era, and by the 4th century A.D. or even earlier, Hindu kingdoms had been established in each area, using Sanskrit as an official language and a south Indian alphabet as official script. Sculpture and architecture, Hindu or Buddhist, of 5th to 7th or 8th century date are closely related to contemporary or slightly earlier Indian types, especially those of eastern, central, and western India in the Gupta period; Indian *śilpaśāstras* must have been in use, and Indian master-craftsmen at work, though local characteristics are already recognizable. After this period there develops in each area a local national culture, with an art somewhat less closely dependent on that of India; these several classical arts, in the period A.D. 800 to the 13th century, have so much stylistic originality as to make the designation "Indian Colonial" inappropriate. Finally after 1300 the culture and art in each area are either undermined by political disturbances, invasion, etc., or develop a provincial character; so far as it has survived to the present day, typically, for example, in Bali, the art becomes a folk-art, and as such deserves high respect and admiration, though it lacks some of the force and monumental qualities of earlier periods. Except in Burma, hardly any trace of painting has survived, so that our account of the most important artistic developments in each area will be essentially a study of the sculpture, the architecture having been treated in another article.

Burma.—The northern area, extending southward as far as Old Prome (Śrīkṣetra) was originally occupied by Pyus, the far south (Thāton) by Talaings, relatives of the Mon-Khmers. Indian colonies had been established in Arakan, Prome, Thāton, and other places; Pali inscriptions in a south Indian character and gold and silver Buddha images in Gupta style have been discovered, and together with other remains, partly Hindu and partly Buddhist, afford evidence of early and strong Indian influence. Burma, however, has always been predominantly Buddhist; Mahāyānist in the north, Hīnayānist in the south. In the 9th century the Talaings captured Prome and established a capital at old Pagan, farther north. Shan-Thai invasions followed, introducing the ancestors of the true modern Burmese, who have gradually

replaced the Pyus and absorbed the Talaings. Pagan became an independent cultural centre, but very few of its countless temples and stupas date before the 11th century.

It is only with the unification of Burma under Anawrata (1040-77) that the great building era was initiated, which covered the Pagān plain with some 5,000 pagodas, as the Buddhist temples and stupas are commonly called. Anawrata conquered Thāton and brought Hīnayāna traditions to the north. The quantity of sculpture extant is not very great, and all that is of real importance dates from the 11th to the 13th century. The finest is the great series of 81 reliefs depicting the life of Buddha according to the *Avidura Nidāna*, set up in the Ananda Pagoda (11th century); animated and exceedingly elegant, they exhibit already the development of a definitely Burmese style, distinct from the earlier, almost purely Gupta tradition. The Brahmanical reliefs of the Nat Hlaung Gyaung are somewhat more Indian. Most of the smaller bronzes and stone reliefs are very closely related to examples of the Pala school of Bihar and Bengal, and some may have been direct importations. A noteworthy phase of Burmese sculpture is represented by the large series of high relief glazed terracotta plaques, which decorate the Schwezigon, Petleik, Ananda and other pagodas, and illustrate *Jātakas*; the art seems to have been introduced from the south.

Several of the Pagān temples contain contemporary paintings. Those of the Kubezatpaya and Kubyaukkyi, illustrating *Jātakas*, consist of small square panels closely grouped, but here and elsewhere there are separate representations of Buddhas and Bodhisattvas on a larger scale. The Minnanthu frescoes illustrate the Tantrik Buddhism of the Ari sects, a mixture of Buddhism and Hinduism, often quite erotic in its symbolism. Frescoes in the Kyanzitthu cave temple represent undoubted Mongols, who invaded Burma at the end of the 13th century. The stylistic affinities of Burmese paintings are with Bengal and Nepal, as exemplified in well known manuscripts of 11th and 12th century date; the outline is wiry and nervous, the hair above the brow descends in a central point, the eyebrows and eyelids are doubly curved; the three-quarter face is often seen, and the markedly projecting farther eye recalls an Indian mannerism that appears already at Elūrā and survives in the Gujarāti painting of the 15th-16th centuries.

After the 13th century the political conditions are more disturbed, the connection with India is not so intimate, and the sculpture and painting become more rigidly stylistic, until an art of purely folk character is developed, and this has survived into the 19th century. Much of the best work in this kind has been done in wood; wood-carving, indeed, became the dominant art of Burma in later times; some of the best examples occur in the elaborate decoration of the wooden monasteries of Mandalay and Amarapura, and also in the ornament of river boats.

Of the minor arts, Burma is famous for its lacquer, applied either architecturally or to small objects for personal or monastic use, the latter including books and book-covers. The smaller objects, baskets, etc., are made of finely plaited bamboo or horse-hair; this foundation is varnished black, other colours are superposed, and by engraving revealed in the required designs. Much of the work is restricted to black and gold; other colours employed are red, green, and yellow. The designs may be geometrical or floral, or when more elaborate, may include figures of divinities or scenes from *Jātakas*.

Siam.—It is of primary importance to realize that the early art of the country now called Siam is not "Siamese," but includes a variety of schools; the Thais or Siamese did not themselves come into possession of the Menam delta before the 13th century, and before this time it is impossible to speak justly of "Siamese" art.

The designation "School of Dvāravatī" applies to remains, mainly of 6th century, found at Brah Pathama (Prapathom), Labapuri, Phong Tuk and other sites around the north-west angle of the gulf of Siam, an area which constituted the Mon kingdom known to the Chinese as Kan To Li and Dvāravatī. Among the sculptures are a finely decorated wheel (Dharmacakra) and standing and seated Buddha figures in stone and bronze, all in a style

closely related to that of the Gupta period in India, as seen at Sārnāth, Mathurā, and Ajanṭā. Brahmanical figures include statues of Viṣṇu with the cylindrical head-dress. All these types correspond in style and date with the "Khmer primitif" or pre-Khmer art of Cambodia. These early sculptures are usually made in a hard bluish limestone. The tradition of the school of Dvāravatī must have persisted until the Khmer invasions of the 11th century, and can perhaps be traced even in the earliest works of the southern Siamese kingdom of Ayuthiā.

The sculptures from Ligor and Jaiyā, in the northern Malay peninsula, a part of the Siamese territory, are now preserved in the museum at Bangkok, but they are rightfully classified as belonging to the school of Śrīvijaya, and will be referred to below under Sumatra.

Khmer influence is not felt until the beginning of the 11th century, with the foundation of a Khmer kingdom at Labapurī; to the Labapurī school belong the characteristic "Siamese" sculptures of Khmer type, dating from the 11th and 12th centuries. Most of these are executed, as in Cambodia, in sandstone; they are almost entirely Buddhist. The majority are somewhat inferior to the actual Cambodian works, but three at least (Coedès, *Collections du Musée National*, Plates XVII.-XXI.) are of superb quality, the most remarkable being the royal portrait said to be that of the legendary king Brahmādatta. In the sculpture of the Labapurī school the classical Khmer type with level brows and eyes, large mouth, and impassable serenity, is easily recognizable, but a certain provincial differentiation can be distinguished, for example in the rather longer and sharper nose, due perhaps already to a certain mixture with native or northern elements. Later Siamese art is in part founded on this Labapurī tradition, as modified by the northern Thai formulae. At this time, however, and up to the 13th century, Lāmbūn in the north remained under Mon rule, as is proved by inscriptions.

Meanwhile Siamese (Thai) Buddhist art had been developing in the extreme north at Xieng Sen, to some extent under Indian Pāla influences passing through Burma. Almost all the northern works are in bronze. The main characteristics are the bulky form, producing an almost feminine type, the arched brows, small mouth, and fleshy chin. About the same time a similar type appears in the far south at Ligor, a fact similarly referable to the widespread Pāla influences exerted at this time.

The classical Thai (Siamese) type was created by the independent kingdom of Sukhodaya (Sukothai-Sawankalok), which came into being only in the middle of the 13th century. It exaggerates the Xieng Sen formulae, but is more refined; it is in every way the opposite of the old Khmer type of Labapurī. The Siamese type established at Sukhodaya is characterized by markedly arched brows, doubly curving upwardly inclined eyelids, an aquiline or even hooked nose, and delicate sharply moulded lips. To this Sukhodaya school and its earliest southern prolongations belong all the finest examples of Siamese art properly so called. Sinhalese influence can also be recognized, confirming literary evidences and tradition; for example, the terminal flame of the *uṣṇīṣa*, characteristic in Siamese art from this time onwards, is of Sinhalese origin, and the engraved *Jātaka* illustrations of Wāt Si Jum at Sukhodaya, of high decorative beauty, but really drawings on stone rather than sculpture, show a decided affinity with the contemporary painting at Poḷonnāruwa in Ceylon.

The Siamese formula extended rapidly to the lower Menam valley with the Thai advance, overlying and profoundly changing the Khmer art of Labapurī. The main developments are represented by the early transitional school of Ū Thong (late 13th and early 14th century) and the later school of Ayuthiā from the middle of the 14th century. By this time, too, the Siamese formula is beginning to exert its influence even in Cambodia. Ayuthiā remained the capital until 1757, the year of the foundation of Bangkok.

The art of the Ayuthiā period, often fine in technique and elegant in form, is on the whole that of a period of decadence; the plastic quality is gradually lost, the forms of the features are accentuated by outlines, and the modelling becomes at last insensitive. But the bronze seated Buddha at Braḥ Mongkol Bopitr,

Ayuthiā, cast probably in the 16th century, and still *in situ*, is a magnificent figure, the largest bronze Buddha in the world, after the Dai Butsu in Japan. Somewhat less interesting, dating from the early 16th century, are the large brass statues of Śiva and Viṣṇu recently rediscovered at Kampeng Brej (Kampeng Phet); these illustrate an occasional tendency to "Khmerism" which appears sporadically even in true Siamese art.

Siamese painting on walls and in illustrated manuscripts is hardly known by extant examples of earlier than 17th or 18th century date, but has a very definite ethnic character, and may be considered of high merit, regarded as a folk rather than as a classic art. Closely related to this painting is the excellent gold lacquer work applied to temple doors and windows, book covers and book chests (fine examples in the royal library, Bangkok). Siamese porcelain is mainly of Chinese origin, that is to say made in China, but in Siamese designs and for the Siamese market; it is gaily enamelled in five colours, and the wares of this type range in date from the 16th century to about 1868. Earlier, about the 13th century, the manufacture of celadon and crackled wares had been established at Sawankalok with good results, and production continued for some time. Of other Siamese arts and crafts, the silverware (filigree, repoussé and niello), jewellery and damascening on steel all maintained a high standard of excellence up to quite modern times. Another craft deserving mention is that of preparing the cut leather figures used in shadow plays.

Cambodia.—Here the record is most complete, extending at least from the 6th to the 14th century. The early or pre-Khmer or Indianesque art (as it is variously called) occurs mainly in the south (Funan), and includes many sculptures in the round and in relief, Buddhist and Brahmanical. Buddha figures of 5th or 6th century dating from Romlok are closely related to Gupta types; the drapery, without indication of folds, clings closely to the body, and the swayed pose vividly recalls the types of Ajanṭā and Sārnāth. A vigorous and powerful Buddha head is in some respects intermediate between Indian and Chinese T'ang types. Even more striking and distinguished are the best of the Brahmanical figures; the Stoclet figure from Phnom Da and also the Harihara from Prasāt Andet may be said to rank amongst the very finest examples of any Indian school. The former is almost unique in pose, and may represent either a deified king, or possible Kṛṣṇa in the act of raising Mt. Govardhana; the figure has a concentration and living quality that are powerfully impressive. The Harihara (union in one person of Śiva and Viṣṇu), if somewhat less animated, has a like simplicity of form, and truly royal dignity. The characteristic cylindrical head-dress is directly of Indian origin; it is worn by kings at Amarāvati, and in earlier Indian art by Indra.

Comparatively little sculpture can be assigned to the disturbed period of the 8th century. With the 9th, we reach what is known as the classical period of Cambodian (Khmer) art, covering nearly five centuries. While cult and mythology are still essentially Indian, a local ethnic type, very definite and unmistakable, is developed, characterized by broadness and straightness of the features. Two special cults are strongly developed, the one that of the worship of deified royal ancestors, represented by images in the form of their patron deity, the other that of the "royal divinity" (Devarāja), represented by a lingam. Apart from these, almost the entire Brahmanical and Buddhist pantheon is represented. Highly characteristic of the later, but not the latest phase of Khmer classical art is the representation of immense faces in relief on the towers of temples and city gateways; these most typically in the Bayon of Añkor Thom, the city to which the seat of government was removed from the adjacent Prah Khan about A.D. 900. The Bayon, c. A.D. 1050, is in many respects the most remarkable, as the later *Añkor Wāt*, c. A.D. 1125, is the most beautiful, of all Khmer buildings. All the great towers have masks on four sides. Besides this, the various chapels held images of Buddhist and Hindu deities, deified ancestors, and the Devarāja. Few of these remain *in situ*, but in addition to those, and to rich floral decorations, the walls of the lower galleries are covered with reliefs representing divinities, epic legends, processions, naval com-

Buddha; Chiang Mai, Siam, 13th-14th cent. 1' 10 1/2". 13. Temptation of the Buddha, Borobudur, Java, 8th cent. 14. Gallery relief, Angkor Wat, Cambodia, 12th cent. 15. Head of Siva or the sage Agastya; Cambodia, 10th cent.

bats, and scenes from contemporary industrial life, as though the founders of Añkor had wished to perpetuate a record of the glory of their state. Bronzes of the classical period have also been found in considerable numbers. Towers with masks crown the triple gateways of the city, and the causeways leading across a moat to these entrances are flanked with parapets consisting of Devas and Yakṣas of colossal proportions supporting the body of a gigantic Nāga, which takes the place of a railing. These Nāga parapets, with or without giant supporters, and terminating in elevated many-hooded heads, are most characteristic of Khmer art. Within the city, the retaining wall of the great terrace, which ran along one side of the public square and in front of the palace, is covered with a continuous series of reliefs representing lions, horses, elephants, Garuḍa caryatides, games and hunting and battle scenes; at one end there is a kind of belvedere, with a retaining wall decorated with successive tiers of seated royal or divine figures; and upon it there still remains *in situ* the nude figure known as the "Leper King," who may have been Yaśovarman, the first ruler of the city.

In the vast number of extant Cambodian temples, and in the museum at Phnom Peñ as well as in French and American museums, there survive innumerable examples of classical Khmer sculpture; amongst the few of the latter which can be localized may be mentioned the seated figure, probably of Sūryavarman I., from Phnom Chisor. The perfect application of the classical art, however, is reached at Añkor Wāt, the later name of the most famous Cambodian temple, a Brahmanical erection of the first half of the 12th century, due to Sūryavarman II. Most of the Buddhist images now to be seen here are of much later date; the sculptural importance of the temple depends on the two great series of reliefs, one widely distributed and decorating wall and pilaster surfaces, the other along the inner wall of the lower galleries surrounding the central mass. Of the former, the most enchanting are the figures of Devatās, often described as dancing girls, though in reality the descendants of the Yakṣis of early Indian art. In the words of a later Cambodian poet (Fang), "one cannot see them thus, so beautifully made, and in the flower of their youth, without adoring them. The eye does not tire, the soul is delighted, the heart is never satisfied. One cannot make up one's mind to leave them. They are no longer figures made by human hands; they are living women, beautiful and gracious." On the other hand the gallery reliefs are heroic, dealing with the battle scenes of the *Rāmāyaṇa* and *Mahābhārata*, cosmic events like the Churning of the Ocean, and images of heaven and hell. In their superb vitality these reliefs are superior to the more exquisite and lovely sculptures of Borobuḍur. That Khmer sculpture maintained a high level of achievement much later is proved by the remains of the temple of Īśvarapura at Bantay Srei, distant 13 m. from Añkor Thom, and of 14th century date. After this, the Khmer régime was altogether broken down by the Siamese conquerors; all that survives to the present day is the great tradition of the theatre and of the sumptuary arts. Cambodian weavers still excel in the weaving of silks in which the threads are parti-dyed before the warp is laid (*chiné* or *ikat* technique), and their productions are amongst the finest textiles still made in the East. Fine work on traditional lines in gold and silver is done, and there exist craftsmen able to cast bronze figures in admirable reproduction of ancient types.

Campā (Annam).—Although the Sanskrit inscription of Vo-canḥ dates back to about A.D. 200, the only really early sculpture is a standing Buddha figure in bronze found at Dong-Duong, this is so closely related in style to the Indian school of Amara-vatī, and to the early sculpture in Ceylon, that it may well have been an importation. Nothing Indianesque in the Gupta style has been found. The best sculptures in stone are the Brahmanical figures (Śiva, Kārttikeya, Gaṇeśa, etc.) from Mi-son, dating partly from the 7th century, and now to be seen in the museum at Tourane. At Dong-Duong, the only Buddhist site in Campā, a colossal broken Buddha still lies amongst the ruins, dating from the beginning of the 10th century. At Po Nagara, a statue of Bhagavatī, which in the 10th century replaced an original lingam, is now worshipped by the Annamites. At Po Klong Garai, the

lingam set up in the 13th or 14th century still receives the offerings of Cam worshippers.

Sumatra and Malaysia.—Little remains in Sumatra proper in the way of sculpture; and the art of the Śailendra period in Central Java (*see below*), though due to Sumatran patronage, must be regarded as essentially Javanese. Beautiful and important sculptures dating from the same period, and quite in the Śailendra style, have been found at various sites in the north of the Malay peninsula, now part of Siam. Towards the end of the 7th century, as is proved by inscriptions, the influence of Śrīvijaya (the name of the Sumatran empire of the Śailendras) was exerted in the region of Ligor and Jaiyā, and this fully accounts for the "Javanese" character of the magnificent bronze figures of Lokeśvara from Jaiyā, now in Bangkok, and for the plan of Wāt Keo at Jaiyā, so like that of Caṇḍi Kalasan in Java. But at these sites there have also been found sculptures much more like those of "pre-Khmer" art in Cambodia, and a Mon-Khmer influence in northern Malaysia must also be allowed for.

Java.—Nothing in the way of sculpture remains from the old Hindu kingdom of Tārumā in western Java; this would have been of the Gupta type. The earliest sculptures are those of the temples of the Dieng plateau, already possessing a definitely Indonesian character. The best, perhaps, are the Brahṃā, Śiva and Viṣṇu reliefs of Caṇḍi Srikandi. Immediately afterwards we come to the extensive monuments of the Śailendra or Sumatran period (c. A.D. 732–860) in middle Java. The earliest of these is Caṇḍi Kalasan, where there remains much beautiful decorative sculpture, but the main image, probably a bronze Tārā, is lost; at Caṇḍi Sāri, however, there are numerous figures in relief. The reliefs of the small chapels of Caṇḍi Sewu at Prambanam are perhaps more beautiful. At Caṇḍi Mendut, near Borobuḍur, the serene and lovely Buddha and Bodhisattva figures are still *in situ*, perfectly preserved, and these are probably the finest examples of middle Javanese sculpture in the round.

At Borobuḍur, sculpture in the round is represented by a great series of seated Buddha figures, placed in niches and in the hollow dagabas on the upper terrace. Varying somewhat in quality, the forms are full and serene rather than strongly energized. Most remarkable is the great series of reliefs illustrating the life of Buddha according to the *Lalitā Vistara*, and edifying legends from the *Divyāvadāna*, *Gaṇḍavyūha*, and *Jātakamālā*, all of which are reproduced and described in the magnificent publications by Krom and Erp. These reliefs are found along the inner sides of the terraced procession paths, and if placed end to end would extend for nearly three miles. The untroubled richness of the forms, the absence of dramatic emphasis, reflect the enormous wealth and security of the Śailendra culture; devotion itself appears rather as culture than as passion; yet the beauty of these reliefs once realized can never be forgotten.

The return of the Javanese kings to Central Java at the end of the 9th century accounts for the great Brahmanical temple complex of Caṇḍi Loro Jongran at Prambanam. Most remarkable here are the reliefs of the terrace of the Śiva temple, illustrating the *Rāmāyaṇa*; fundamentally in the same style as those of Borobuḍur, they are more animated and more dramatic, as is perhaps natural having regard to their heroic theme. After 915 Central Java was for long completely deserted, and the continuation of the art history must be sought in the east, under the kings of Kediri, Singasari and Majapahit.

A remarkable "portrait" figure of Erlanga (A.D. 1010–42) near Belahan takes the form of a representation of Viṣṇu riding on Garuḍa, a true masterpiece of vigorous sculpture. Singasari in the 13th century has yielded numerous magnificent sculptures, including figures of Gaṇeśa, Durgā, Mañjuśrī and the goddess Prajñāpāramitā; the last, now in Leyden, is one of the most famous pieces of Javanese sculpture, though in reality somewhat lacking in vitality and over-refined. Really more significant, though already remote from the classic tradition, are the *wayang* (leather puppet-like) reliefs of Caṇḍi Jago, illustrating the *Kṛṣṇāyaṇa*, a rather unexpected theme in a Buddhist temple, but exemplifying the profound intermixture of Brahmanical and Buddhist cult which had already taken place in Java, as in Nepal and Cambodia,

and as still surviving in Bali. Here, and more conspicuously in the later (14th to 15th century) reliefs of Panataran, illustrating the same theme and the *Rāmāyana*, there becomes apparent a passing over of the classical tradition into a purely folk art, and the emergence of an indigenous Malay-Polynesian ethnic factor in which the stylistic inheritance of India is almost overwhelmed. After the 15th century, when almost all Java had accepted Islam, this later folk art continued to flourish in Bali, and has survived there up to the present day.

Borneo.—A handsome standing bronze Buddha from Kota Bangoen has long been known, and is now to be seen in the museum at Batavia. More recently, there have been found in the Koetei district of Middle East Borneo, in the caves of Kombeng, where they were perhaps hidden about 1600 when Islam prevailed in Borneo, numerous sandstone images, both Brahmanical and Buddhist; the former include figures of Śiva, Kārttikeya, Gaṇeśa, Agastya, etc., the latter various Bodhisattvas, or perhaps deified royal ancestors. Further, amongst the crown jewels of Koetei is a gold pendant consisting of a standing figurine of Viṣṇu, four-armed, and flanked by a pair of Garuḍas. These remains show that eastern Borneo too was at one time the seat of a Hinduized kingdom.

The iconography of the images is a little confused, and their style somewhat provincial, but the best examples are of really fine quality. The bronze Buddha shows clear traces of the Indian Gupta style. Taken all together, the sculptures show a close stylistic connection with those of the Dieng plateau and Borobudur in Java, and they may be regarded as the products of a local school in Borneo, dating from the Śailendra epoch in Java, and for the most part referable to the 7th or 8th century. (See also INDIAN ARCHITECTURE; INDIAN AND CEYLONESE ART AND ARCHAEOLOGY; TEXTILES; BATIK.)

INDORE, an Indian State in the Central India agency, comprising the dominions of the Maharaja Holkar. Its area, exclusive of guaranteed holdings on which it has claims, is 9,519 sq.m. and the population in 1921 was 1,151,598. As in the case of most

states in Central India the territory is not homogeneous, but distributed over several political charges. The Vindhya range traverses the southern division of the state from east to west, a small part of the territory lying to the north of the mountains, but by far the larger part to the south. The latter is a portion of the valley of the Nerbudda, and is bounded on the south by the Satpura hills. Basalt and other volcanic formations predominate in both ranges, although there is also much sandstone. The Nerbudda flows through the state.

The state had its origin in an assignment of lands made early in the 18th century to Malhar Rao Holkar, a peasant's son who worked his way up to a cavalry command in the army of the Marhatta peshwa. Of the Dhangar or shepherd caste, he was born in 1694 at the village of Hol near Poona, and from this circumstance the family derives its surname of Holkar. Before his death in 1766 Malhar Rao had added to his assignment large territorial possessions acquired by his armed power during the confusion of the period. By the end of that century the rulership had passed to another leader of the same clan, Tukoji Holkar, whose son, Jaswant Rao, took an important part in the contest for predominance in the Marhatta confederation. At first he defeated a British force that had marched against him under Colonel Monson; but when he made an inroad into British territory he was completely defeated by Lord Lake in 1804, and compelled to sign a treaty which deprived him of a large portion of his possessions. In 1818, by the treaty of Mandason, the state transferred to the British government its suzerainty over a number of minor tributary states, and acknowledged the British protectorate. For many years afterwards the administration of the Holkar princes was troubled by intestine quarrels, misrule and dynastic contentions, necessitating the frequent interposition of British authority; and in 1857 the army, breaking away from the chief's control, besieged the British residency. In 1899 a British resident was appointed, and a change was made in the system of administration, which was from that date carried on by a council. Of its last two rulers, one abdicated in 1903 and his successor in 1926. The present Maharaja was born in 1906. His salute is 19 guns.

The CITY OF INDORE (pop. 93,091) is situated 1,738 ft. above the sea, on the river Saraswati, near its junction with the Khan. It is one of the most important trading centres in central India, with flourishing cotton-mills, a good hospital and college, besides palaces and gardens.

East of the city lies the British Residency, an area reserved by treaty under British jurisdiction. The Resident and his staff live here, and it is the site of the Daly college, a fine marble building, for the education of young Indian princes and nobles.

INDORSEMENT or ENDORSEMENT: see BILL OF EXCHANGE.

INDO-SCYTHIANS, a name commonly given to various tribes from central Asia, who invaded northern India and founded kingdoms there. They comprise the Sakas, the Yue-Chi or Kushans, and the Ephthalites or Hūnas.

INDRA, in Vedic Hindu mythology god of the clear sky and greatest and best of deities; he is lauded in some 300 hymns (or quite a fourth of the *Rig-Veda*). Unquestionably of Zoroastrian origin, the Boghaz Keui inscription (c. 1400 in Asia Minor) mentions Indra with Varuna and Asvins, but in the *Avesta* he appears as a demon. In the *Vedas* however his paternity is ascribed to Dyaus, the Sky, and he is almost the national god of the invading Aryans. Represented as having four arms and hands, in two he holds a spear and in a third a thunderbolt, his body is depicted as Sahasrakhsa, "with 1,000 eyes." In the epic age Indra survives as one of the eight great Devas, but is gradually subordinated to Brahma, Siva and Vishnu, and in modern Hinduism he is merely vicegerent of Swarga the heaven of the gods.

INDRE, a department of France, formed in 1790 from parts of the old provinces of Berry, Orléanais, Marche and Touraine. Pop. (1926) 255,095. Area 2,666 sq.m. It is bounded north by the department of Loir-et-Cher, east by Cher, south by Creuse and Haute-Vienne, south-west by Vienne and north-west by Indre-et-Loire. The department slopes north-westwards from the Plateau Central and is drained by the river Indre. In the north is the

Champagne, a land of corn and of sheep with fine wool; in the west is the Brenne, once marshy, now drained and afforested; the wooded Boisshot is in the south, east and centre. The average annual temperature is nearly three degrees higher than that of Paris, but the winter on the higher Boisshot is somewhat severe. The average rainfall is $23\frac{1}{2}$ inches. Wheat and oats are largely grown, as are beetroots and artichokes. Wool-spinning and weaving and iron-working are the chief industries; felt hats and parchment are made.

The department is divided into the arrondissements of Châteauroux, the capital, le Blanc and la Châtre, with 23 cantons and 247 communes. It is in the archbishopric of Bourges, where is the court of appeal; it is in the region of the IX. Army Corps (Tours), and of the académie (educational division) of Poitiers. At Neuvy-St. Sépulchre there is an 11th century circular church with a 12th century nave; at Mézières-en-Brenne a 14th century church; at Levroux a 13th century church, and the remains of a feudal fortress; and a magnificent Renaissance château at Valençay. St. Genou has an 11th century church and a 12th century tower. There are several dolmens in the department.

INDRE-ET-LOIRE, a department of France, consisting of nearly the whole of the old province of Touraine and of small portions of Orléanais, Anjou and Poitou. Pop. (1926) 334,486. Area 2,377 sq.m. It is bounded north by the departments of Sarthe and Loir-et-Cher, east by Loir-et-Cher and Indre, south and south-west by Vienne and west by Maine-et-Loire. The department is floored by the southern outcrop of Eocene of the Paris basin, with barren shell-marl at Sainte-Maure between the Indre and the Vienne; the Loire and its affluents, the Cher, Indre and Vienne, cut valleys with fertile slopes through these Eocene deposits. North of the Loire is the barren Gâtine; between Cher and Indre the vine-clad slopes of Champeigne; between the Loire and Vienne the vine- and fruit-growing Véron sloping down to the Val d'Anjou; and in the south the Brenne (*see* INDRE). The climate is mild with average annual temperature 1.8° F. above that of Paris, and about 24 in. of rainfall. Cereals, potatoes, hemp, beetroot and the vine are grown, and many sheep reared. There are quarries of building- and mill-stones. The industries include iron and lead working, potteries, silk-spinning and weaving, important tanneries and the making of famous wines.

Indre-et-Loire is divided into the arrondissements of Tours and Chinon, possessing 24 cantons and 282 communes. The chief town is Tours, which is the seat of an archbishopric; the court of appeal is at Orléans, and the department is in the region of the IX. Army Corps (Tours) and of the académie (educational division) of Poitiers. Chinon, Loches, Amboise, Chenonceaux, Langeais and Azay-le-Rideau are also important. Montbazou has the ruins of a square donjon of the 11th and 12th centuries. Preuilly has the most beautiful Romanesque church in Touraine. The Sainte Chapelle (16th century) at Champigny is a survival of a château of the dukes of Bourbon-Montpensier. The church of Montrésor (1532) has the mausoleum of the family of Montrésor. The town of Richelieu, founded in 1631 by the famous cardinal, preserves its enceinte and many 17th century buildings. Megalithic monuments are numerous.

INDRI, the largest of the existing lemurs. Belonging to the family *Lemuridae* (*see* PRIMATES) it typifies the subfamily *Indrisinae*, which includes the avahi and the sifakas (*q.v.*). From both these it is distinguished by its rudimentary tail, measuring only a couple of inches in length, whence its name of *Indris brevicaudatus*. It measures about 24 in. in length, exclusive of the tail; its colour varies, but it is usually black, with a number of whitish patches. It inhabits the forests of a small tract on the east coast of Madagascar; shoots, flowers, and berries form its food.

INDUCTION, means sometimes generalization; sometimes the whole series of steps by which a generalization is discovered and established (that is, the processes of observation, formation of hypothesis, verification of hypothesis by further observations or experiments, and formulation of the generalization in a manner that will best fit all the observations and experiments); and sometimes the term is used in a still wider sense for any attempt

to discover any kind of order or connection between certain facts, whether it results in a generalization or not. Now the various methods by the aid of which the attempt is usually made to trace order and connection in phenomena are known as the methods of science, and are described in the article SCIENTIFIC METHOD (*q.v.*). Here it is only necessary to discuss some of the more general aspects and problems of induction, more especially its logical basis or justification.

Logical Basis of Induction.—Generalization is probably as old as human thought. In fact, the tendency to rash generalization would seem to be one of the original sins of mankind. It is one side of the formation of habits. When a certain number of things have been observed to have certain attributes, uncritical people form the habit of expecting all such things to have those attributes. Witness the reckless way in which such people generalize about the characters of whole peoples, after a superficial acquaintance with a very few representatives. Similarly, where certain events have been observed to occur at the same time, or in rapid succession, they are apt to be regarded as uniformly connected. It is in this way that the numerous superstitions have originated. Mankind did not have to wait for the growth of the scientific spirit to learn to generalize; it only had to wait, and still waits, for the growth of the scientific frame of mind in order to learn to check that rash tendency, and to tread warily in order to reach *legitimate* generalizations.

Early thinkers like Aristotle attempted to check the tendency to rash generalization by setting up a severe standard, and insisting that the ideal of generalization is what is still known as "perfect induction," that is, generalization based upon an exhaustive examination of the whole group or class of facts concerned. No doubt it would be a great boon to mankind if people refrained from generalizing about whole countries or communities until they knew every citizen or member thereof. But then the ideal of perfect induction has made no impression on practical people, and has proved to be worthless as a guide for scientific people. In the vast majority of cases the classes of objects and events with which science is concerned are far too numerous to permit anything even distantly approaching exhaustive individual examination of all the members. All the important inductions of science are what used to be called imperfect inductions, that is to say, generalizations based on the examination of a bare sample of the whole class under investigation. And its great problem has been, and still is, how to excuse, or to justify, such extensive generalizations after the study of but a few instances or specimens. To this question various answers have been attempted, and the most important of them may now be considered briefly.

One answer, which is rather in favour among some of the more philosophical of contemporary men of science, is to the effect that there is really no justification for induction. All inductions, and all forecasts based on them, are just more or less sanguine adventures, or speculations. And the fact that they do not always disappoint us is nothing short of marvellous. It is just like drawing a cheque on a bank and finding it honoured, although one has no reason for thinking that he has a balance there. This kind of agnostic solution, if it may be called a solution, is not really satisfactory. It practically amounts to giving up the problem as hopeless. After all, in this as in other matters, it is the business of the investigator to interpret nature in the light of the clues she affords. If a bank honours one's cheque, one does not marvel at it, but draws certain conclusions about one's balance or one's credit. If nature fulfils anticipations based on inductions, some inference might be drawn about her character or constitution.

Law of Succession.—Another answer given, and one that is much in favour among certain statisticians and other mathematically minded people, is based on what is known as the law of succession. Assuming that all generalization is essentially of the artless type mentioned above, and commonly known as induction by simple enumeration, the solution now under consideration bases itself on the calculus of probability, and correlates the reliability of the generalization with the number and kind of observations made. Each observed occurrence of an event in certain

circumstances is treated as a point in favour of expecting its recurrence in similar circumstances. However, the probability diminishes for every increase in the number of recurrences contemplated. Thus if the event in question has been observed m times and has failed to occur x times, then the probability of r recurrences will be expressed by the formula $(m+1)/(m+x+r+1)$, which is known as Laplace's Law of Succession. If the number of occurrences observed (m) is very large, and if no exceptions are known (i.e., $x=0$), and if one contemplates just one recurrence (i.e., $r=1$), then the probability may approximate certainty, for $(m+1)/(m+r+1)$ will in that case nearly $=1$, i.e., certainty (see PROBABILITY). But now in a real scientific generalization (say, e.g., the Law of Gravitation, or the Laws of Motion), the number of recurrences contemplated (r) is practically infinite, so that its probability, according to the above formula, cannot really be high, even at the best. Moreover, on what rational grounds can a previous occurrence be regarded as a reason for its recurrence, as distinguished from our spontaneous expectation of it? This solution, too, cannot therefore be regarded as satisfactory.

J. S. Mill based all induction on the principle of the uniformity of nature, but his conception of this was not very satisfactory. For, on the one hand, he regarded this assumed objective uniformity, in the character and connections of natural phenomena, as the ground of all induction, and, on the other hand, he regarded it as being itself a very comprehensive induction based upon numerous other inductions each much more limited in scope. This ambiguous attempt to make the same principle at once the foundation and the roof of this whole structure of science has not been received with favour. But it may be reasonably interpreted, perhaps, as meaning that we start with the assumption of the existence of uniformities among natural phenomena, that we justify all actual generalizations on the strength of this assumption, but that, on the other hand, the very success of the numerous generalizations made may be regarded as a kind of verification (and, in that sense, as a ground) of the principle itself. This, at all events, would afford some explanation of the unexplained marvel referred to in the agnostic answer already stated above. And, in any case, it seems impossible to dispense entirely with some such postulate as that of the uniformity of nature, even if we also admit that by itself it does not help us to discover, or to test, any actual generalization. In this respect we need also the postulate or principle of fair samples, that is, the assumption that, with reasonable care, it is possible to judge the character of a large group, or of a whole class, of phenomena by means of a sample selected with discrimination.

Perhaps the least unsatisfactory way of answering the general question as to the logical ground of induction, using this term in its widest sense for every attempt to trace order in nature, is on the following lines. The scientific search for order among natural phenomena would seem to assume the existence of order there. Science does not propose to invent it and impose upon nature, only to discover it, if possible. This search does not necessarily presuppose a definite conviction that what is sought is actually there. One may look for what is hoped for, or for what is deemed probable, as well as for what is definitely expected to be there. Moreover, to assume that there is some order in nature is not the same thing as to suppose that nature is orderly through and through.

After all the world is vast, and the field of actual scientific investigation is comparatively limited, so it is always open to the man of science to select for his field of research some class of facts in which the discovery of order looks fairly promising. On the whole, experience has shown that there is some order in nature, indeed, sufficiently so to justify and encourage the continued search for more. Turning to the question of the ground of generalization more particularly, one must, in the first place, distinguish between those which rest on induction by simple enumeration only, and those which are based ultimately on one of the induction methods, especially when these can be applied with some rigour, and not rather loosely. Inductions based on simple enumeration, and even statistical generalizations must

always be regarded with a measure of diffidence. They may indicate temporary or partial conjunctions rather than general connections. It is rather different in those cases in which the inductive methods have been applied (whether in the form in which J. S. Mill has formulated them, or in some similar form).

Even in such cases, it is true, what the method applied really proves is that in the particular instance observed, or experimented with, a certain phenomenon was causally connected with a certain other phenomenon. It does not by itself prove the generalization that those two kinds, or classes, of phenomena are causally connected. But we are so constituted that, wittingly or unwittingly, we assume what has been called the principle of the uniformity of reasons, which states that "whatever is regarded as a sufficient reason in any one instance is regarded as a sufficient reason in all instances of that type." If in a particular case it appears, through the application of one of the inductive methods, that d as such was causally connected with z , then d must be assumed to be always causally connected with z , and in this way we arrive at the generalization. The extreme sceptic or agnostic may dismiss this principle as a mere prejudice or defect of human intelligence. But is it so unreasonable to suppose that human intelligence has gradually and painfully been shaped so as to fit the constitution of nature?

See SCIENTIFIC METHOD and the bibliography given there. For induction in mathematics see MATHEMATICAL INDUCTION.

(A. Wo.)

INDUCTION COIL, an electrical instrument for producing high electromotive force, consisting of two coils of wire wound one over the other on a core formed of a bundle of thin iron wires or a number of thin iron sheets. An induction coil is thus essentially an electromagnet with two windings called the primary and secondary coils. The action of induction coils depends upon the effect known as electromagnetic induction, discovered by Faraday in 1831. (See ELECTRICITY.) If an electric current in the primary coil is caused to vary rapidly, a current is induced in the secondary which, flowing to its terminals, produces temporarily an accumulation of electricity on and near them and a high potential difference between them. The variation of the primary current is usually effected by "interrupting" this current, i.e., by breaking the connection between the primary coil and the source of current supply. In some applications of induction coils, however, the primary coil is supplied with alternating current, and the action is then similar to that of a transformer (*q.v.*). Induction coils are largely used in X-ray work in which very high voltage is required to produce the discharge through the tube in which the X-rays are generated. A few years ago, in the early days of wireless telegraphy, induction coils were much used for actuating the transmitting apparatus. They are still employed in connection with the production of high frequency discharges for medical purposes. Small induction coils are used in very large numbers for producing the sparks required for ignition in internal combustion engines.

The history of the induction coil begins in Nov. 1831, when Faraday described an experiment (*Phil. Trans. R.S.*, 1832; and *Experimental Researches*, vol. i.) in which two coils of wire were wound on an iron ring and insulated from each other. Faraday observed that if the terminals of one of the coils were brought near each other, short sparks appeared between them when a current was started or stopped in the other coil. Soon afterwards other experimenters began to develop this method of producing high potential effects, among them Joseph Henry, C. G. Page, N. J. Callan, and William Sturgeon. It was soon found that the effects could be obtained with coils wound on a straight iron core, and that a core made up of a bundle of thin iron wire was more effective than one consisting of a single bar of iron. Before 1840 the automatic mercury, or platinum contact, interrupter, actuated by the intermittent magnetization of the core, had come into use. No further marked improvement was effected till 1853, when Fizeau added the condenser, connected to the terminals of the interrupter, which greatly increased the length of spark obtainable with induction coils. About the same time Ruhmkorff, in Paris, introduced several improvements, especially in connection with the insulation of the secondary wire. He also increased the number

of turns in the secondary coil, and wound it on a glass tube to improve its insulation from the primary coil. Ruhmkorff also adopted in his later coils the method (previously suggested by E. and C. Bright) of winding the secondary coil in numerous flat sections instead of arranging it in layers extending over the whole length of the coil, the object being to keep as far apart as possible windings which are at a great difference of potential.

During the period 1867-1900 several very large induction coils were made by different manufacturers for the purpose of producing sparks of great length. One of these, made by A. Apps, for the old Polytechnic Institution of London, had a core of iron wire 5 ft. long, and a secondary wire 150 m. in length. This coil gave sparks 30 in. long. A still larger coil, made by Apps for Spottiswoode, and now preserved at the Royal Institution, London, had a secondary coil of 341,850 turns, the total length of the wire being 280 miles. With a battery of 30 Grove cells, sparks 42 in. long could be obtained with this coil. Very large coils have also been made by Klingelfuss, of Basle, who employed an improved method of sectional winding of the secondary coil. The wire is wound in one continuous length and, by the use of separating discs of stepped form, the thickness of the insulation between neighbouring turns of consecutive sections is graded in accordance with their difference of potential. Induction coils made by this firm are notable for their comparatively small number of secondary turns, one of them, with only 86,000 turns, producing sparks 1 metre long. A coil made by the same firm for the Paris Exhibition of 1900 gave sparks 150 cm. (59 in.) long. During this period induction coils came much into use in experimental work, especially in connection with the discharge of electricity through gases, and with the production of electrical oscillations, and they were instrumental in such important discoveries as the Hertzian waves, the cathode rays, and the Röntgen rays.

In large modern induction coils, such as those used for the production of X-rays, the cores are usually built of long strips of thin transformer sheet insulated from one another, the length of the core being 10 to 15 times its diameter. On the core, and well insulated from it, is wound the primary coil, the thickness of the copper wire depending upon the current to be used in operating the coil. The primary coil is sometimes arranged in three or four sections which, by means of a commutator, can be connected in series or in parallel. The core and primary coil are placed within a thick-walled tube of micanite or other material of great dielectric strength, upon which is placed the secondary coil of no. 36 or no. 32 silk-covered copper wire. There is considerable diversity in the method of winding the secondary coil. Some makers arrange the coil in thin flat sections only one wire thick, separated from one another by discs of insulating material. Others prefer to wind the coil in sections, three or four wires thick. In either case the separating discs should be wide enough to extend well beyond the inner and outer boundaries of the sections, so that the wire can be well surrounded by insulating material, and the whole should be thoroughly impregnated with insulating wax.

Several modern coils are arranged in only two or four sections, each section wound in layers, on the grounds that with this construction the windings are less likely to become displaced, and that the turns having the highest potential can be kept furthest away from the primary coil. As an alternative to impregnation with wax the plan of immersing the coil in insulating oil contained in a metal or porcelain vessel has come into use in recent years. Such oil-immersed coils are usually placed with their axes vertical. The dry type of coil is usually covered with a sheet of ebonite and mounted on a base board, or is cast in solid wax in a wooden case.

Improved forms of hammer break, with platinum contact pieces, are still used with small coils, but with large coils a motor-driven mercury interrupter is much more suitable. The most effective form of mercury interrupter is that known as the "turbine," or "jet" type, in which a pair of revolving jets of mercury, pumped up by the rotation from the bottom of an iron container, make contact during their rotation with two or more metal plates. The jets are diametrically opposite to each other, and the two plates with which they simultaneously make contact are connected

to the source of current supply. A diagram of the circuits of an induction coil is shown in fig. 1.

In early forms of mercury jet interrupters the jet and plate were immersed in oil or alcohol, but coal gas is now generally used as the insulating medium in which the interruption takes place. As many as 150 breaks per second may be produced with this particular type of interrupter. Sometimes the motor of a mercury jet interrupter is also used for driving a rectifier, or rotating commutator, connected in the secondary circuit for the purpose of eliminating the reverse potential induced in the secondary when the primary circuit is "made." This reverse potential at "make" is usually very small in comparison with the direct potential at "break," but when the coil is operated by a battery or other source of high voltage, it may be sufficient to produce some discharge the wrong way through an X-ray tube.

If very high rates of interruption are required an electrolytic interrupter, devised by Wehnelt in 1899, may be employed. This consists of a plate of lead immersed in dilute sulphuric acid, and a platinum wire protruding a short distance from a porcelain tube. When this is connected in series with the primary coil, with the platinum wire to the positive pole of the battery, the current becomes rapidly intermittent owing to the successive formation of gas bubbles, the frequency being sometimes over 1,000 per second.

A very important application of the principle of the induction coil is found in the *high tension magneto*, which consists essentially of a very small induction coil mounted on an armature rotated in the field of a permanent magnet, the current in the primary coil being generated by the rotation, and being interrupted by a contact breaker at a suitable point in each revolution. Another form of induction coil, usually called an oscillation transformer, is the Tesla coil, which is used for generating currents of high frequency and high voltage. It consists of a primary coil, having a few turns of thick copper wire, connected in series with a Leyden jar and a spark-gap, and a secondary coil having a large number of turns of finer wire. A succession of sparks is produced at the spark-gap by an ordinary induction coil, each spark giving rise to a group of high frequency oscillations which produce remarkable brush discharge and other effects in and near the terminals of the secondary coil. Similar effects are produced with the *auto-transformer*, a single coil of bare copper wire wound on an ebonite frame and having a few turns at one end connected to the Leyden jar and spark-gap so as to form the primary circuit. The remainder of the coil forms the secondary winding. In this arrangement the primary and secondary influence each other not only by magnetic action but also in consequence of the electrical connection between them.

Theory of the Induction Coil.—The theory is much simplified by the fact that the iron core usually forms a very "open" magnetic circuit, so that the magnetic flux in it is, over a wide range, approximately proportional to the current flowing in either of the coils. The self inductances, which we will denote by L_1 and L_2 , may therefore be treated as constant. The mutual inductance may also be regarded as constant but, owing to the fact that the secondary current is not distributed uniformly along the secondary wire, the coefficient of inductance of the primary on the secondary is greater than that of the secondary (for unit current in its central winding) on the primary. These two coefficients will be denoted by L_{21} and L_{12} . If the capacities in the primary and secondary circuits are C_1 , C_2 , the relation between the potentials V_1 and V_2 , in the two circuits is expressed by the equations

$$L_1 C_1 \frac{d^2 V_1}{dt^2} + L_{12} C_2 \frac{d^2 V_2}{dt^2} + R_1 C_1 \frac{dV_1}{dt} + V_1 = E,$$

$$L_2 C_2 \frac{d^2 V_2}{dt^2} + L_{21} C_1 \frac{d^2 V_1}{dt^2} + R_2 C_2 \frac{dV_2}{dt} + V_2 = 0;$$

FROM JONES, "THEORY OF THE INDUCTION COIL" (PITMAN & SONS, LTD.)

FIG. 1.—DIAGRAM OF THE CIRCUITS OF AN INDUCTION COIL

where R_1 , R_2 are the resistances of the circuits and E is the battery electromotive force. If the resistances are neglected these two equations can be easily solved, and the result shows that the wave of potential in each circuit, after the interruption of the primary current, consists of two simple harmonic components differing in amplitude and frequency. Each of the two frequencies of the system depends upon the inductances and capacities of both circuits.

If the frequencies are represented by n_1 , n_2 (n_2 being the greater), the expression for the potential at the terminals of the secondary coil at any time t after the interruption of the primary current i_0 is

$$V_2 = \frac{2\pi L_{21} i_0 n_1 n_2}{n_2^2 - n_1^2} (n_2 \sin 2\pi n_1 t - n_1 \sin 2\pi n_2 t).$$

This expression shows that the two components of the potential wave in the secondary circuit begin from zero in the opposite phase, and that their amplitudes are inversely proportional to their frequencies. In fig. 2 are shown the potential waves for four different values of the frequency ratio n_2/n_1 .

FROM JONES, "THEORY OF THE INDUCTION COIL" (PITMAN & SONS, LTD.)

FIG. 2.—WAVES OF POTENTIAL IN AN INDUCTION COIL FOR DIFFERENT VALUES OF THE FREQUENCY RATIO n_2/n_1

The upper curves show the two components separately, the lower curves the result of their superposition, i.e., the actual wave of potential in the secondary circuit. It will be seen that when the frequency ratio is 3 or 7, maxima of the two component waves occur simultaneously, giving a specially high voltage at this moment. This also happens when n_2/n_1 has one of the values 11, 15, etc. When the frequency ratio is 5 or 9, a minimum of the more rapid component coincides with a maximum of the slower, resulting in a reduced value of the maximum voltage. In these latter cases there are, in fact, two equal peaks in the potential wave, one occurring before, the other after, the maximum of the slower component. The curves in fig. 2 cover only one half-period of the slower component; their continuation in the second half-period is a repetition with the ordinates changed in sign. Curves similar to the lower curves of fig. 2 can be obtained experimentally by the use of a suitable oscillograph. An example is given in fig. 3, a photograph of the wave of potential at the secondary terminals of an induction coil as indicated by an electrostatic oscillograph connected directly with them.

The instrument was of the kind in which the deflection is proportional to the square of the potential, consequently the deflections are in the same direction for both positive and negative parts of the wave. The form of the first half-wave of the curve shows that the ratio of the two frequencies was very nearly 7, as in the third of the lower curves in fig. 2. The wavy line below the oscillograph curve in fig. 3 represents the oscillations of a tuning fork, each wave in this line corresponding to $\frac{1}{788}$ second.

FROM "PHILOSOPHICAL MAGAZINE" (TAYLOR & FRANCIS)

FIG. 3.—ACTUAL OSCILLOGRAPH RECORD OF POTENTIAL AT TERMINALS OF SECONDARY

The foregoing expression for V_2 enables us to calculate the effect of varying one or other of the "constants" of the circuits, for example, the capacity C_1 of the condenser connected to the interrupter. The result of such a calculation is shown in the full-line curve of fig. 4, in which the abscissa is proportional to the primary capacity—it represents, in fact, the ratio $L_1 C_1 / L_2 C_2$ —and the ordinate is proportional to the maximum secondary potential. In this example the coupling (defined as $L_{21} L_{12} / L_1 L_2$) is 0.835.

It will be seen that the curve of secondary potential consists of portions of a series of arches, all lying within and all except one touching the broken line curve which represents the sum of the amplitudes of the two potential oscillations in the secondary circuit. As the primary capacity is increased from zero, the frequency ratio n_2/n_1 , diminishes from infinity, and, at the four points of

contact of the full-line and broken-line curves in fig. 4, n_2/n_1 , has the values 19, 15, 11 and 7. At the points of intersection of the arches the frequency ratios are 17, 13, 9 and 5. One of the points of contact ($n_2/n_1=7$) occurs at the summit of the broken line curve, and it therefore represents a very favourable adjustment of the circuits for producing high secondary voltage. Not only is the potential equal to the sum of the amplitudes of the two components, but the sum of the amplitudes also has its maximum value in this adjustment. These favourable conditions do not occur at all values of the coupling, but only at certain values, four of which are 0.571, 0.835, 0.902 and 0.931. If the coupling k^2 has one of these values, the optimum primary capacity is that which makes $L_1 C_1 = (1 - k^2) L_2 C_2$, and the maximum secondary voltage is then $i_0 \sqrt{L_{21} / L_{12}} \sqrt{L_1 / C_2}$. The form of the curve showing the relation between primary capacity and secondary potential depends upon the coupling. In fig. 5 is shown a curve obtained by experiment with a coil the coupling of which was 0.767.

FROM JONES, "THEORY OF THE INDUCTION COIL" (PITMAN & SONS, LTD.)

FIG. 4.—CALCULATED CURVE SHOWING EFFECT OF VARYING THE CAPACITY OF THE PRIMARY CONDENSER

Abscissae are proportional to primary capacity, ordinates proportional to maximum secondary potential. Coupling=0.835

The ordinate of this curve represents the reciprocal of the least primary current the interruption of which causes a spark to appear at a spark-gap connected with the secondary terminals, and it is therefore proportional to the maximum secondary potential for a given primary current. The extreme arch on the right of this curve is more prominent than that of fig. 4, and at values of the coupling below 0.71 the right-hand arch is higher than all the others. It follows that as the coupling is reduced the frequency ratio necessary for maximum secondary potential also becomes smaller, e.g., when the coupling is 0.571, the primary capacity should be so adjusted that the frequency ratio is 3.

Damping of the Oscillations.—In this sketch of the theory we have neglected the resistances of the circuits and other causes of dissipation of energy. In practice, owing to the resistances and the leakage and core losses (see ELECTROMAGNET), the oscillations are subject to decay factors; they die away just as do the vibrations of a tuning fork after it is struck. This damping of the oscillations is clearly shown in fig. 3. In a good modern coil the maximum secondary voltage may be reduced by over 25% by the losses, which are, however, not sufficient to affect to any great extent the frequencies of the oscillations or the conditions in which maximum voltage is produced.

When a spark or other form of discharge is allowed to pass

FROM JONES, "THEORY OF THE INDUCTION COIL" (PITMAN & SONS, LTD.)

FIG. 5.—EXPERIMENTAL CURVE SHOWING VARIATION OF MAXIMUM SECONDARY POTENTIAL WITH PRIMARY CAPACITY. COUPLING=0.767

between the secondary terminals, the theory hitherto described, with allowance for the damping of the oscillations, is applicable up to the moment at which the discharge begins. The ordinary spark discharge of an induction coil, in air at atmospheric pressure, generally consists of an initial true spark followed by an arc. In the initial spark, which represents the discharge of the electricity accumulated on the secondary coil, and which probably contains a train of high frequency oscillations, the potential falls very rapidly to a small value, and thereafter the secondary current flows as an arc in the conducting path prepared for it by the initial

spark. In the arc the current usually pulsates with a period dependent upon the constants of the primary circuit and the coupling, the approximate expression for the period being $2\pi\sqrt{L_1C_1(1-k^2)}$.

The total quantity of electricity passing in the ordinary spark discharge depends upon the length of the spark and upon the current interrupted in the primary circuit. It increases with the current, though not in proportion to it, and it diminishes as the length of the spark is increased. When the discharge takes place through a "soft" X-ray tube the secondary voltage again follows the course indicated by the foregoing theory up to the moment at which the discharge begins. During the discharge the potential falls, not with great rapidity as in the spark discharge, but much more gradually, and with fluctuation, to a smaller value at which the discharge ceases. After this the system continues to oscillate, with what energy it has left, in the two frequencies which it possesses when the secondary circuit is open. In the case of discharge through an ordinary high resistance, the discharge current consists of two damped oscillatory components if the resistance is sufficiently high; but if the resistance is below a certain value, one of the oscillations becomes replaced by aperiodic components.

Theory of the Tesla Coil.—This is somewhat similar to that of the induction coil, the chief difference arising from the fact that the oscillations are started in a different way. The potential in the secondary of a Tesla coil is the result of the superposition of two oscillations differing in frequency but having the same amplitude. The two oscillations begin in opposite phase but not from zero, i.e., they begin at their maximum positive and negative values. In order to produce the highest potential at the secondary terminals of a given Tesla coil, operated by sparking across a given gap, the Leyden jar should have a capacity considerably greater than that which satisfies the resonance condition $L_1C_1=L_2C_2$, i.e., the condition which makes the periods of oscillation of the primary and secondary circuits equal when they are separated. In the ordinary induction coil worked by an interrupter the primary capacity which gives the highest secondary voltage is, as we have seen, much smaller than the value which makes L_1C_1 equal to L_2C_2 .

INDULGENCE, a term defined by the official catechism of the Roman Catholic Church in England as "the remission of the temporal punishment which often remains due to sin after its guilt has been forgiven." This remission may be either total (*plenary*) or partial, according to the terms of the Indulgence. (Lat. *indulgentia*, *indulgere*, to grant, concede.)

The theory of Indulgences is based by theologians on the following texts: 2 Samuel (Vulgate, 2 Kings) xii. 14; Matt. xvi. 19 and xviii. 17, 18; 1 Cor. v. 4, 5; 2 Cor. ii. 6–11; but the practice itself is confessedly of later growth. As the primitive practice of public penance for sins died out, there grew up a system of equivalent, or nominally equivalent, private penances. Just as many of the punishments enjoined by the Roman criminal code were gradually commuted by mediaeval legislators for pecuniary fines, so the years or months of fasting enjoined by the earlier ecclesiastical codes were commuted for proportionate fines, the recitation of a certain number of psalms, and the like. The practice of Indulgences in the mediaeval church arose out of the authoritative remission, in exceptional cases, of a certain portion of this canonical penalty.

The first definite instance of a *plenary* Indulgence is that of Urban II. for the First Crusade (Council of Clermont, Mansi, *Concilia*, xx. 816): "Whoever, out of pure devotion and not for the sake of gaining honour or money, shall go to Jerusalem to liberate the church of God, may count that journey in lieu of all penance" (1095). A little earlier had begun the practice of *partial* Indulgences, which are always expressed in terms of days or years.

However definite may have been the ideas originally conveyed by these notes of time, their first meaning has long since been lost. The rapid extension of these time-Indulgences is one of the most remarkable facts in the history of the subject. Innocent II., dedicating the great church of Cluny in 1132, granted as a great favour a forty days' Indulgence for the anniversary. A hundred years later, all churches of any importance had similar Indulgences; yet Englishmen were glad even then to earn a pardon of forty days by the laborious journey to the nearest cathedral, and by making an offering there on one of a few privileged feast-days. A century later again, Wycliffe complains of Indulgences of two thousand years for a single prayer (ed. Arnold, i. 137). In 1456, the recitation of a few prayers before a church crucifix earned a Pardon of 20,000 years for every such repetition (Glassberger in *Analecta Franciscana*, ii. 368); and at length Indulgences were so freely given that there was now scarcely a devotion or good work of any kind for which they could not be obtained. It must be noted that, according to the orthodox doctrine, not only can an Indulgence not remit future sins, but even for the past it cannot take full effect unless the subject be truly contrite and have confessed (or intend shortly to confess) his sins. This salutary doctrine, however, was obscured by the phrase *a poena et a culpa*, which, from the 13th century to the Reformation, was applied to Plenary Indulgences. The *prima facie* meaning of the phrase is that the Indulgence itself frees the sinner not only from the temporal penalty (*poena*) but also from the guilt (*culpa*) of all his sins. "The laity cared little about the analysis of it, but they knew that the *a culpa et poena* was the name for the biggest thing in the nature of an Indulgence which it was possible to get" (Father Thurston in *Dublin Review*, Jan. 1900.) It is recorded that during the Jubilee of 1300, all the Papal Penitentiaries were in doubt about the meaning of the words and appealed to the Pope. Boniface VIII. did indeed take the occasion of repeating (in the words of his Bull) that confession and contrition were necessary preliminaries; but he neither repudiated the misleading words nor vouchsafed any clear explanation of them. The phrase exercised the minds of canonists all through the middle ages, but still held its ground. The most accepted modern theory is that it is merely a catchword surviving from a longer phrase which proclaimed how, during such Indulgences, ordinary confessors might absolve from sins usually "reserved" to the Bishop or the Pope. However it originated, it undoubtedly contributed to foster popular misconceptions as to the intrinsic meaning of Indulgences, apart from repentance and confession though Dr. Lea seems to press this point unduly (p. 54, seq.), and should be read in conjunction with Thurston (p. 324, seq.). These misconceptions were widespread from the 13th to the 16th century, and were often fostered by the "pardoners," or professional collectors of contributions for Indulgences. This can best be shown by a few quotations from eminent churchmen during those centuries. Berthold of Regensburg (c. 1270) says, "Fie, penny-preacher! . . . thou dost promise so much remission of sins for a mere halfpenny or penny, that thousands now trust thereto, and fondly dream to have atoned for all their sins with the halfpenny or penny, and thus go to hell" (ed. Pfeiffer, i. 393). A century later, the author of *Piers Plowman* speaks of pardoners who "give pardon for pence poundmeal about" (i.e., wholesale; B. ii. 222); and his contemporary, Pope Boniface IX., complained of their absolving even impenitent sinners, for ridiculously small sums (*pro qualibet parva pecuniarum summula*, Raynaldus, *Ann. Ecc.* 1390). In 1450 Thomas Gascoigne, the great Oxford Chancellor, wrote: "Sinners say nowadays 'I care not how many or how great sins I commit before God, for I shall easily and quickly get plenary remission of any guilt and penalty whatsoever (*cujusdam culpae et poenae*) by absolution and indulgence granted to me from the Pope, whose writing and grant I have bought for 4d. or 6d. or for a game of tennis'"—or sometimes, he adds, by a still more disgraceful bargain (*pro actu meretricio*, Lib. Ver. p. 123, cf. 126). In 1523 the princes of Germany protested to the Pope in language almost equally strong (Browne, *Fasciculus*, i. 354). In 1562 the Council of Trent abolished the office of "pardoners."

See H. C. Lea, *Hist. of Auricular Confession and Indulgences in the*

Latin Church (Philadelphia, 1896); his standpoint is frankly non-Catholic, but he gives materials for judgment; T. Brieger, art. "Indulgenzen" in Herzog-Hauck, *Realencyklopädie* and A. Boudinhon, art. "Indulgences" in Hastings' *Ency. of Religion*. The greatest orthodox authority is Eusebius Amort, *De Origine indulgentiarum* (1735). More easily accessible are Father Thurston's *The Holy Year of Jubilee* (1900); F. E. Hagedorn, *General Legislation on Indulgences* (1924); *Johannis Hus tractatus responsivus*, now first edited by S. Harrison Thomson (1927); and art. "Indulgences" in the *Catholic Encyclopedia*.

INDULINES, dark blue dyestuffs belonging to the azine class. (See DYES, SYNTHETIC.)

INDUNA, a Zulu-Bantu word for an officer or head of a regiment among the Kafir (Zulu-Xosa) tribes of South Africa. It is formed from the inflexional prefix *in* and *duna*, a lord or master.

INDUS, one of the three greatest rivers of northern India. Its sources are in the glaciers of the Himalayan peaks of the Kailas group, which overlook the Mansarowar lake and the sources of the Brahmaputra, the Sutlej and the Gogra to the south-east. Three affluents, flowing north-west, unite about 80° E. to form the main stream. At Leh, the Ladakh capital, the river has already run north-westerly for 300 m., except for a divergence to the south-west, which carries it through the Ladakh range, about 100 m. above Leh, to follow the same course on the southern side that had been maintained on the north. For another 230 m. the Indus pursues a comparatively placid north-western course over its sandy bed between the giant chains of Ladakh to the north and Zaskar (the main "snowy range" of the Himalaya) to the south, through magnificent mountain scenery. Then the river receives from the north the waters of the Shyok (a tributary nearly as large as itself), having already been augmented by the Zaskar from the south, together with innumerable minor glacier-fed streams.

The Shyok rises near the southern foot of the Karakoram pass on the high road between Ladakh and Kashgar, drains the southern slopes of the Karakoram range and then breaks across the axis of the Muztagh chain, before bending north-westward to run parallel to the Indus for 150 m. before its junction with that river. The combined stream still flows north-west for another 100 m., under the shadow of a vast array of snow-crowned summits, until it arrives within sight of the Rakapushi peak, midway between Gilgit and Hunza. Here occurs a change of direction to the south-west, which is thereafter maintained till the Indus reaches the ocean. At this point it receives the Gilgit river from the north-west, having dropped from 15,000 to 4,000 ft. (at the junction of the rivers) after about 500 m. of mountain descent through the northern Kashmir. It continues through mountainous country till it emerges into the plains of the Punjab below Dardband, in 34° 10' N.

There are a few native bridges in the upper course, and a wooden bridge at Leh. There are iron bridges above Bunji and at Attock, where the valley narrows almost to a gorge, 900 ft. above sea-level. Twenty miles below Attock the river has carved out a central trough believed to be 180 ft. deep. Forty miles below Attock a bridge carries the railway to Kohat and the Kurram valley; and at Mari, beyond the series of gorges which continue from Kushalgarh to the borders of the Kohat district there is a boat-bridge. Another boat-bridge opposite Dera Ismail Khan connects that place with the railway. The Lansdowne bridge at Sukkur is one of the greatest triumphs of Indian bridge-making. Kotri is connected with Hyderabad in Sind, and the Indus is now one of the best-bridged rivers in India. The river is navigated in the plain by high-sterned flat native boats.

In Sind there is much variation in the channel beds within the outside banks of the river. In prehistoric days a branch found its way to the Runn of Cutch, and the gradual shift of the river westward led later to the disappearance of many populous places which were more or less dependent upon it for their water supply. The greatest change was caused when the stream broke through the limestone ridges of Sukkur and assumed a course which has been fairly constant for nearly two centuries. These variations are due largely to the fact that the Indus carries down sufficient detritus to raise its own bed above the general level of the surrounding plains. At present the bed of the river is stated to be

70 ft. above the plains of the Sind frontier, some 50 m. W. of it.

The total length of the Indus, measured directly, is about 1,500 m., and the area of its basin is computed at 372,000 sq.m. Even at its lowest in winter it is 500 ft. wide at Iskardo (near the Gilgit junction) and 9 or 10 ft. deep. At Attock, where the river narrows between rocky banks, a height of 50 ft. in the flood season above lowest level is common, with a velocity of 13 m. per hour. At its junction with the Panjnad (the combined rivers of the Punjab east of the Indus) the Panjnad is twice the width of the Indus, but its mean depth is less, and its velocity little more than one-third. Below the junction the united discharge in flood season is 380,000 cubic ft., rising to 460,000 (the record in August). Unusual floods, owing to landslips or other exceptional causes, are not infrequent.

The naturally arid lands of Sind depend largely for their prosperity upon the waters of the Indus. Canals from the river irrigated nearly 3,000,000 acres in 1926, but their water-supply fluctuates with the rise and fall of the river. A vast scheme was therefore undertaken to ensure a continuous supply; it includes a barrage in the gorge below Sukkur, three weirs on the Sutlej, and one on the Panjnad. The scheme is designed to command an area of 7,500,000 acres, and to irrigate over 5,000,000 in British territory, Bikaner and Bahawalpur. The Thal irrigation project, also in hand, is intended to irrigate nearly 2,000,000 acres from the Indus on and about the watershed between that river and the Jhelum.

INDUSTRIA (mod. *Monteu da Po*), an ancient town of Liguria, 20 m. N.E. of Augusta Taurinorum. Its original name was Bodincomagus, from the Ligurian name of the Padus (mod. Po), Bodincus, *i.e.*, bottomless, and this still appears on inscriptions of the early empire. It stood on the right bank of the river, which has shifted over 1 m. to the north. It was a flourishing town, as excavations (which have brought to light streets, the forum, theatre, baths, etc.) have shown, but was deserted in the 4th century A.D.

INDUSTRIAL ACCIDENTS. In the term industrial accident, the adjective implies that the accident results in injury to a person and has some causal connection with work, employment or occupation. The relevant wording of the Workmen's Compensation Act, 1923, of Great Britain runs "... accident arising out of and in the course of employment"; this definition has been incorporated in laws enacted in the British Dominions and the United States, while in other countries the definition though different in wording is similar in intent. There is a distinct tendency towards making the term cover several "health risks" also, for these, though "accidental" only in a limited sense, have an eminently "industrial" character. Experience shows that industrial accidents (including industrial diseases) occur with great regularity in all industries and cause a loss to persons engaged in it. They therefore constitute a risk to labour. This risk may be regarded under different aspects. First, it may be qualified as an "economic risk"; secondly, accidents imply a human cost, a "personal risk," because attended with physical and mental suffering, both on account of the injury itself and because wage earners exposed to the risk generally have a very small margin between income and necessary expenditure.

Frequency of Industrial Accidents.—The frequency of accidents is shown by relating the number of accidents to "accident exposure." The simplest measure of the exposure is the number of workers employed in the industry concerned. When the industry is large and the period covered long (*e.g.*, one year), allowance should be made for the irregularity of employment, and for this reason the accident exposure may be expressed in terms of the "number of full-time workers," *i.e.*, those who would have been employed, had all employees worked regularly during the whole possible working time (in practice, the number of man-days divided by 300). A similar result is secured by the method (devised in the United States) of expressing the accident exposure in terms of the man-hours worked; the frequency rate is then the number of accidents per 1,000 workers employed, or per 1,000 full-time workers, or per 1,000,000 man-hours.

Statistics.—It would be very instructive to compile an inter-

national survey of the number and frequency of industrial accidents in the chief countries. Unfortunately, the statistics as published to-day are still far from comparable, and in most cases international comparisons would be positively misleading. The main sources of incomparability are the following: (a) different scope of the statistics; (b) different definition of accidents covered; (c) different standards of reporting; and (d) different calculation of the accident exposure.

For Great Britain, no comprehensive statistics of all industrial accidents exist. The statistics of workmen's compensation cover seven principal groups of industries, and all accidents disabling for at least three days and for which compensation was paid for the first time during the year. It is estimated that not more than half of the employees under the Workmen's Compensation Act are thus covered by the statistics, the principal exclusions being the building industry, agriculture and domestic service. The figures for 1926 are as follows:

Great Britain: Frequency of Industrial Accidents, 1926

Industry	Number of persons employed	Number of accidents		Rate of accidents per 1,000 persons	
		Fatal	Non-fatal	Fatal	Non-fatal
<i>Shipping, total</i>	203,340	333	6,175	1.64	30.37
Steam vessels	198,860	311	5,922	1.56	29.78
Sailing vessels	4,480	22	253	4.91	56.47
<i>Factories, total</i>	5,207,735	724	165,122	.14	31.71
Cotton	550,234	34	10,226	.06	18.58
Wool, worsted, shoddy	254,472	17	3,451	.07	13.56
Other textiles	208,495	3	2,105	.01	10.10
Wood	126,821	33	5,317	.26	41.93
Metals(extraction,etc.)	330,134	79	24,096	.24	72.99
Engine and shipbuilding	382,088	113	19,677	.30	51.50
Other metal work	801,263	154	30,858	.19	46.00
Paper and printing	335,900	21	4,806	.06	14.58
China and earthenware	70,497	17	1,356	.24	19.23
Miscellaneous	2,147,822	253	57,140	.12	26.60
<i>Docks</i>	127,606	112	10,987	.88	86.10
<i>Mines</i>	772,883	787	88,770	1.02	114.86
<i>Quarries</i>	77,791	62	5,668	.80	72.86
<i>Constructional work</i>	111,705	72	7,270	.64	65.08
<i>Railways, total</i>	500,735	228	17,614	.46	35.18
Clerical staff	85,302	2	205	.02	2.40
Other railway servants	415,433	226	17,409	.54	41.91
Grand total, 1926	7,001,793	2,318	301,606	.33	43.08
Grand total, 1925	7,541,014	2,989	403,826	.40	53.55

In the United States, too, no statistics for all jurisdictions and all industries are compiled. Summing up the information available for 38 States in 1925, it is found that the total number of fatal cases was 10,537, and that of non-fatal cases, 1,687,957. It should be noted that these figures exclude agriculture, domestic service, maritime and railway employments in all States, and all accidents in 14 States and territories. More accurate statistics are compiled for a few important industries; the number and the frequency rate per 1,000 full-time workers in 1925 were as follows:

United States: Industrial Accidents, 1925

Industry	Number of full-time workers	Number of accidents		Rate of accidents per 1,000 full-time workers	
		Fatal	Non-fatal	Fatal	Non-fatal
Coal mines	480,227	2,234	..	4.65	..
Metal mines	123,908	321	35,132	2.99	283.53
Quarries	83,487	149	14,105	1.78	169.67
Iron and steel	445,223	207	36,465	0.46	81.90

The total number of employees killed in steam railway accidents in 1925 was 1,594, and of those injured, 118,874; the frequency rates among trainmen were 2.14 fatal and 87.66 non-fatal cases per 1,000 men in service.

The German statistics cover practically all industries except small undertakings and domestic service, agriculture being given apart. In 1926, the number of insured persons in industries was 10,794,031, the number of fatal accidents, 5,429, and that of non-fatal accidents, 826,899, the rates being 0.50 fatal and 76.61 non-fatal cases per 1,000 persons; in agriculture, there were 14,068,000 insured persons; 2,682 fatal and 176,119 non-fatal cases; or 0.19 and 12.52 cases respectively per 1,000 persons. In France, the total number of accidents in all industries, including agriculture, commerce, transport and domestic service, but excluding mines and railways, in 1926 was 2,392 fatal and 981,244 non-fatal; the number of coal-mining accidents (in 1925) was 354 fatal and 93,516 non-fatal, while the railway employees sustained (in 1923) 387 fatal and 615 severe non-fatal accidents. The situation in a small highly industrialized country is illustrated by the Belgian statistics; they covered (in 1921) 601,841 workers and recorded 209 fatal and 95,146 non-fatal accidents, i.e., 0.35 fatal and 158.09 non-fatal cases per 1,000 workers.

There is one important industry in respect of which an international comparison may be attempted, viz., coal-mining. Owing to the fact that work underground involves quite particular occupational risks, and coal-mining actually is the most hazardous industry (with the possible exception of shipping), special statistics relating thereto are more developed than others. The accident exposure may be expressed for the several countries in uniform terms (though in Germany allowance is not made for overtime). Nevertheless, the reporting of accidents is different, and while the fatal accident rates are fairly comparable, those of non-fatal cases are less so. The figures for 1925 are as follows:

Coal Mining: Frequency of Accidents in Various Countries, 1925

Country	Number of full-time workers	Number of accidents		Rate of accidents per 1,000 full-time workers	
		Fatal	Non-fatal	Fatal	Non-fatal
Belgium	163,061	147	..	0.90	..
Canada (1926)	21,853	77	2,580	3.52	118.06
France	277,603	354	93,516	1.28	336.87
Germany (Prussia)	489,463	1,320	96,429	2.70	197.01
Great Britain	931,700	1,128	177,347	1.21	190.34
Saar Territory	64,343	63	2,824	0.98	43.89
United States	480,227	2,234	..	4.65	..

Finally, as regards industrial diseases assimilated to industrial accidents, the scope of the statistics is determined by the diseases compensated. The most comprehensive statistics are those for Great Britain which cover 32 diseases. The total number of cases for which first payment was made in the seven groups of industries was in 1925, 41 fatal, 8,792 non-fatal, in 1926, 27 fatal, 5,816 non-fatal. The bulk of these cases (87 and 79 per cent. respectively) occurred in the mining industry, and the considerable decrease noted in 1926 is largely due to the long coal stoppage in that year.

In Germany, the statistics refer to 11 diseases; the total number of cases reported in the year 1925-26 was 3,310, of which 2,781 (72 per cent.) were due to lead poisoning. In France, only two industrial diseases are compensated; in 1925 there were 1,343 cases of lead poisoning and 5 of mercury poisoning of occupational origin.

Severity of Industrial Accidents.—The severity of an accident means the extent of resulting incapacity for work. In order to calculate the severity of a group of accidents, it is first necessary to determine the extent of disability in each case. The main categories of disability are (i.) fatal, (ii.) non-fatal, distinguishing between (a) permanent, and (b) temporary disability.

The British statistics do not contain precise information as to the extent of disability caused by accidents, beyond the distinction between fatal and non-fatal cases. According to an estimate, based on the statistics of several other European countries, of the general distribution of industrial accidents usually reported, less than 1 per cent. result in death, about 5 per cent. in perma-

nent disability, and about 94 per cent. in temporary disability. It should, however, be remembered that both from the human and the economic point of view, the few cases of death or permanent disability of high degree are of more importance than the bulk of minor accidents. This point is the basis of the calculation of "severity rates," which show the number of working days lost on account of accidents, related to the accident exposure.

In order to know the working time lost, an arbitrary value is fixed for cases of death (6,000 days lost in the United States, 7,500 days in Sweden and Switzerland); the time loss entailed by permanent disability is assessed at a given fraction of this basic value (e.g., loss of a thumb equal to 600-1,000 days lost); the time loss resulting from temporary cases is recorded directly. The accident exposure is the number of workers or "full-time workers" or man-hours, as in the case of frequency rates.

The severity rate gives a truer idea of the actual risk of industrial accident than the frequency rate; but it is rather troublesome to calculate, and has therefore as yet been employed neither in the British nor in most other statistics. The following instances drawn from the American records will illustrate the results which have been obtained by the calculation of severity rates as compared with those given by frequency rates. In the United States iron and steel industry, during the five-year period 1920-24, the total number of full-time workers was 1,839,818, and the number of cases, as well as the frequency and severity rates per million hours' exposure, were as follows:

	Number	Frequency rate	Severity rate
Death	1,345	0.2	1,500
Permanent disability	4,810	0.9	800
Temporary disability	179,128	32.5	500
Total	185,283	33.6	2,800

The United States National Safety Council has calculated on similar lines the accident experience of 13 industries employing 828,028 workers and 74,367 cases of accident for 1925. The frequency and severity rates per million man-hours were as follows:

United States: Frequency and Severity Rates, 1925

Industry	Number of accidents covered	Frequency rate	Severity rate
Mining	6,851	99.99	8,510
Quarry	744	48.56	7,640
Construction	1,778	69.54	7,570
Cement	2,541	26.08	5,000
Woodworking	3,087	44.20	2,750
Chemical	2,597	20.91	2,710
Petroleum	5,855	27.35	2,330
Paper and pulp	4,021	38.43	2,150
Metals	21,492	32.50	1,820
Packers and tanners	1,425	40.15	1,270
Rubber	5,054	29.15	1,110
Automotive	17,861	23.42	1,060
Textile	1,061	13.61	450
Total	74,367	30.60	2,020

Causes of Industrial Accidents.—The principal causes of accidents in factories and workshops are shown in the report for 1924 of the Chief Factory Inspector of Great Britain (covering 157,835 accidents) and in the reports for the same year of compensation authorities of 21 American States (covering 838,042 accidents); the figures in the table in next column represent percentages of all accidents.

As regards particularly coal-mining accidents, the statistics show that the largest part of them are due to falls of roofs (in 1926, 33 per cent. in Great Britain; 43 per cent. in the United States), haulage and explosions underground coming next. The accidents to railway employees are classed in the British statistics in (i.) "train accidents," mostly caused by collisions and derailments; (ii.) "movement accidents," the most frequent causes of which are shunting operations, including coupling and uncoupling of vehicles, working on permanent way, and attending to engines

Causes of Accidents (percentages)

	Great Britain	United States (21 States)
Machinery	23.4	17.1
Transport, vehicles	1.0	9.4
Hot or corrosive substances	6.1	4.9
Handling of tools or articles	27.7	28.6
Struck by falling body	13.2	13.3
Persons falling	12.3	9.6
Electricity, explosions, fires, gas-sing	1.1	..
Other	15.2	17.1
Total	100	100

in motion; and (iii.) "non-movement accidents" attributable particularly to loading and unloading of wagons, attending to engines at rest, falling of wagon doors and lamps, working on the line, etc. In the American statistics, accidents to (i.) trainmen, occur most frequently to the class of brakemen (55 cases per million hours' exposure, the general average being 30), while accidents to (ii.) non-train employees are principally attributable to handling (7.4 out of 20.7 cases per million hours). It may be noted that shunting operations present a conspicuously high risk, a fact which has given rise to the question of introducing automatic couplings for trains. Finally, the British statistics of shipping accidents for the 5-year period 1921-25 show that the yearly average of accidental deaths amongst the crews of (mercantile and fishing) vessels was 724, of which 327 were due to casualties to vessels and 395 to other accidents at sea or in river or harbour.

These classifications, however, do not refer to "causes" properly so-called. The determination of the real and most important causes is a difficult task, but it may be briefly stated that each accident is the outcome of a long train of events which is ultimately traceable to some failure of human foresight or insight. Accident statistics have attempted to find out these ultimate causes on two different lines.

Some earlier statistics classified accidents by what may be called their "moral causes" or responsibility for the occurrence of accidents. For instance, according to the German statistics for 1907, 12 per cent. of accidents were attributed to the fault of the employer, 41 per cent. to that of the worker, 7 per cent. to both of them or to a third person, while in not less than 40 per cent. of cases no fault was established.

The failure of care, attention and skill which underlies the occurrence and incidence of the great majority of accidents, results from the combined action of numerous factors, one of the most important of which is inexperience. Evidence obtained from the American metal trades shows that the accident frequency of new workers engaged diminished rapidly from week to week and from month to month, so that the accident rate during the first week was 90 times higher than six months later, while, among men having worked for six months, it was 2.5 times higher than among those employed for from three to five years. Further, accident frequency is larger during the night than the day, night work being always more or less abnormal. Experiments made in the British munition factories during the World War and in the American iron and steel industry showed that the hour-to-hour accident incidence was almost completely reversed during the day and during the night; the day accident rate reached its maximum toward the end of the shift, while the night rate fell for the most of the shift. Hence it appears that the accident incidence is influenced by the mental state of the workers rather than fatigue. Fatigue, however, also plays a part in accident causation when working hours are particularly long, e.g., in docks and railway service, and when heavy muscular effort is required, especially in the case of women. On the other hand, alcoholism has been found to be a potent cause of accidents, especially chronic alcoholism, i.e., excessive regular indulgence; excessive drinkers have been found to be about three times more liable to accident than other persons.

Consequences of Industrial Accidents.—The consequences resulting from industrial accidents may be studied from three

different points of view, viz., medical, economic, and financial.

In order to elucidate the medical consequences of accidents the resulting injuries are to be classified according to their anatomic and clinical character, i.e., their "location" and "nature." According to the statistics of some European countries and several American States as to the location of injury, the parts of the body most commonly affected are upper extremities, viz., arms, hands and fingers (40 to 50 per cent. of all injuries) and lower extremities (20 to 30 per cent.). With regard to the nature of injury, the most usual cases appear to be abrasions, contusions and bruises (25 to 50 per cent. of all injuries) and cuts, punctures and lacerations (25 to 30 per cent.).

By the economic consequences are meant the loss of working days and loss in earning capacity of the injured persons. With a view to showing the consequences of accidents taken as a group, in this respect, these are classified according to the "extent" and "degree of disability." The main classification by the extent of disability was discussed above in connection with accident severity. The "degree of disability" is fixed according to different criteria in different groups of disabilities. In fatal cases it is indicated by the age of the killed person; moreover, these cases are classified by the number of his dependents. Non-fatal cases resulting in "permanent disability" are often classified according to the percentage of incapacity for work, total disability (e.g., loss of both eyes) being taken as equal to 100. Cases of "temporary disability" which form about 94% of all accidents, are subdivided according to the number of working days lost. According to an estimate based on the statistics of a number of countries, this loss is in one-third of the cases less than a week; in two-thirds, less than a month; and in about 95% of cases, less than three months.

Finally, industrial accidents involve important financial consequences. The loss of earnings consequent upon industrial accidents affects in the first place the workers, but a part of this loss is, in practically all countries, a charge on the employers in virtue of workmen's compensation and accident insurance legislation; moreover, the State participates in many countries by bearing the cost of the administration of insurance institutions. International comparisons are still less feasible in this field than in other parts of accident statistics, and for several countries, e.g., the United States and France, no information is available. In Great Britain, the regular statistics only show a part of the cost; a recent official estimate, however, puts the total charge on employers in 1925 (including compensation, administrative expenses, commissions, profits, etc.) at £12,117,000. In Germany, the total of payments of the industry and of the State to the accident insurance institutions was in the same year RM. 266,916,000 (£12,934,000). And it should be remembered that these amounts represent hardly more than one-third to one-half of the aggregate burden which industrial accidents constitute on labour and industry as a whole.

PREVENTION OF ACCIDENTS IN AMERICA

The prevention of industrial accidents, or as it is popularly termed in the United States, "industrial safety work," is that activity undertaken by the employer or in some cases by groups of employers, to remove the physical causes of accidents and to encourage safe practices by the employees. Estimates show that between 23,000 and 25,000 persons meet their death annually as a result of industrial accidents, while approximately 3,250,000 receive non-fatal injuries from the same cause. The economic cost of accidents in industry is placed at \$1,000,000,000 annually. The industrial accident situation, therefore, presents a social problem of considerable importance, as well as a great economic problem.

To the employee an accident means the loss in income equal to the difference between his pre-accident wage and his accident compensation or the wage he is capable of earning after the injury. To the employer, accidents mean the expenditure of funds for the payment of compensation awards, medical and burial expenses or insurance premiums to cover the same. They also mean the permanent or temporary loss of valuable employees; the demoralization of the working force; damaged equipment, raw material and finished product; and curtailed production. These latter items, it has been computed, represent a charge equal to at least four times the cost of compensation and medical service or insurance premiums. To the general public, industrial accidents mean an increase in the cost of living, as the expenses of the manufacturer are included in the cost of producing his product.

In the early years of accident prevention work in industry, it was considered largely a duty of the mechanical engineer in designing and erecting guards and protective devices and making provision for the greater physical safety of the workman. In some cases such activities were required by State law. In other cases, encouragement was given by insurance carriers through their plan of offering credits on premiums. It soon became apparent, however, that human defects and failures were accountable for a much larger proportion of accidents than were mechanical defects. In 1928, statistics indicated that between 80 and 85% of all industrial accidents are due to unsafe practices, while only 15 to 20% are chargeable to unsafe conditions. Methodical education, therefore, is the governing principle in the prevention of industrial accidents.

A study of successful industrial accident prevention work shows that the best results have been obtained in organizations where safety activities, both mechanical and educational, are considered as a direct function of supervision, rather than as a welfare activity, independent of production. It has been the experience of many organizations that the degree of success resulting from the safety plans is dependent in large part upon the amount of direct personal interest taken in this phase of operation by the chief executive. To the employees and supervisors, he is representative of the company and his interests and activities reflect the policy of the employing organization. In the majority of larger plants or companies, however, the chief executive cannot give personal direction to this because of many other duties. In such cases it is customary to assign this work to some other official, sometimes with a supporting staff, to direct the safety activities. In some organizations the safety engineer is placed on the staff of the personnel director. Regardless of the type of organization, however, it is considered important that the individual in charge of safety be given a position on the company's staff, which

nent disability, and about 94 per cent. in temporary disability. It should, however, be remembered that both from the human and the economic point of view, the few cases of death or permanent disability of high degree are of more importance than the bulk of minor accidents. This point is the basis of the calculation of "severity rates," which show the number of working days lost on account of accidents, related to the accident exposure.

In order to know the working time lost, an arbitrary value is fixed for cases of death (6,000 days lost in the United States, 7,500 days in Sweden and Switzerland); the time loss entailed by permanent disability is assessed at a given fraction of this basic value (e.g., loss of a thumb equal to 600-1,000 days lost); the time loss resulting from temporary cases is recorded directly. The accident exposure is the number of workers or "full-time workers" or man-hours, as in the case of frequency rates.

The severity rate gives a truer idea of the actual risk of industrial accident than the frequency rate; but it is rather troublesome to calculate, and has therefore as yet been employed neither in the British nor in most other statistics. The following instances drawn from the American records will illustrate the results which have been obtained by the calculation of severity rates as compared with those given by frequency rates. In the United States iron and steel industry, during the five-year period 1920-24, the total number of full-time workers was 1,839,818, and the number of cases, as well as the frequency and severity rates per million hours' exposure, were as follows:

	Number	Frequency rate	Severity rate
Death	1,345	0.2	1,500
Permanent disability	4,810	0.9	800
Temporary disability	179,128	32.5	500
Total	185,283	33.6	2,800

The United States National Safety Council has calculated on similar lines the accident experience of 13 industries employing 828,028 workers and 74,367 cases of accident for 1925. The frequency and severity rates per million man-hours were as follows:

United States: Frequency and Severity Rates, 1925

Industry	Number of accidents covered	Frequency rate	Severity rate
Mining	6,851	99.99	8,510
Quarry	744	48.56	7,640
Construction	1,778	69.54	7,570
Cement	2,541	26.08	5,000
Woodworking	3,087	44.20	2,750
Chemical	2,597	20.91	2,710
Petroleum	5,855	27.35	2,330
Paper and pulp	4,021	38.43	2,150
Metals	21,492	32.50	1,820
Packers and tanners	1,425	40.15	1,270
Rubber	5,054	29.15	1,110
Automotive	17,861	23.42	1,060
Textile	1,061	13.61	450
Total	74,367	30.60	2,020

Causes of Industrial Accidents.—The principal causes of accidents in factories and workshops are shown in the report for 1924 of the Chief Factory Inspector of Great Britain (covering 157,835 accidents) and in the reports for the same year of compensation authorities of 21 American States (covering 838,042 accidents); the figures in the table in next column represent percentages of all accidents.

As regards particularly coal-mining accidents, the statistics show that the largest part of them are due to falls of roofs (in 1926, 33 per cent. in Great Britain; 43 per cent. in the United States), haulage and explosions underground coming next. The accidents to railway employees are classed in the British statistics in (i.) "train accidents," mostly caused by collisions and derailments; (ii.) "movement accidents," the most frequent causes of which are shunting operations, including coupling and uncoupling of vehicles, working on permanent way, and attending to engines

Causes of Accidents (percentages)

	Great Britain	United States (21 States)
Machinery	23.4	17.1
Transport, vehicles	1.0	9.4
Hot or corrosive substances	6.1	4.9
Handling of tools or articles	27.7	28.6
Struck by falling body	13.2	13.3
Persons falling	12.3	9.6
Electricity, explosions, fires, gas-sing	1.1	..
Other	15.2	17.1
Total	100	100

in motion; and (iii.) "non-movement accidents" attributable particularly to loading and unloading of wagons, attending to engines at rest, falling of wagon doors and lamps, working on the line, etc. In the American statistics, accidents to (i.) trainmen, occur most frequently to the class of brakemen (55 cases per million hours' exposure, the general average being 30), while accidents to (ii.) non-train employees are principally attributable to handling (7.4 out of 20.7 cases per million hours). It may be noted that shunting operations present a conspicuously high risk, a fact which has given rise to the question of introducing automatic couplings for trains. Finally, the British statistics of shipping accidents for the 5-year period 1921-25 show that the yearly average of accidental deaths amongst the crews of (mercantile and fishing) vessels was 724, of which 327 were due to casualties to vessels and 395 to other accidents at sea or in river or harbour.

These classifications, however, do not refer to "causes" properly so-called. The determination of the real and most important causes is a difficult task, but it may be briefly stated that each accident is the outcome of a long train of events which is ultimately traceable to some failure of human foresight or insight. Accident statistics have attempted to find out these ultimate causes on two different lines.

Some earlier statistics classified accidents by what may be called their "moral causes" or responsibility for the occurrence of accidents. For instance, according to the German statistics for 1907, 12 per cent. of accidents were attributed to the fault of the employer, 41 per cent. to that of the worker, 7 per cent. to both of them or to a third person, while in not less than 40 per cent. of cases no fault was established.

The failure of care, attention and skill which underlies the occurrence and incidence of the great majority of accidents, results from the combined action of numerous factors, one of the most important of which is inexperience. Evidence obtained from the American metal trades shows that the accident frequency of new workers engaged diminished rapidly from week to week and from month to month, so that the accident rate during the first week was 90 times higher than six months later, while, among men having worked for six months, it was 2.5 times higher than among those employed for from three to five years. Further, accident frequency is larger during the night than the day, night work being always more or less abnormal. Experiments made in the British munition factories during the World War and in the American iron and steel industry showed that the hour-to-hour accident incidence was almost completely reversed during the day and during the night; the day accident rate reached its maximum toward the end of the shift, while the night rate fell for the most of the shift. Hence it appears that the accident incidence is influenced by the mental state of the workers rather than fatigue. Fatigue, however, also plays a part in accident causation when working hours are particularly long, e.g., in docks and railway service, and when heavy muscular effort is required, especially in the case of women. On the other hand, alcoholism has been found to be a potent cause of accidents, especially chronic alcoholism, i.e., excessive regular indulgence; excessive drinkers have been found to be about three times more liable to accident than other persons.

Consequences of Industrial Accidents.—The consequences resulting from industrial accidents may be studied from three

different points of view, viz., medical, economic, and financial.

In order to elucidate the medical consequences of accidents the resulting injuries are to be classified according to their anatomic and clinical character, i.e., their "location" and "nature." According to the statistics of some European countries and several American States as to the location of injury, the parts of the body most commonly affected are upper extremities, viz., arms, hands and fingers (40 to 50 per cent. of all injuries) and lower extremities (20 to 30 per cent.). With regard to the nature of injury, the most usual cases appear to be abrasions, contusions and bruises (25 to 50 per cent. of all injuries) and cuts, punctures and lacerations (25 to 30 per cent.).

By the economic consequences are meant the loss of working days and loss in earning capacity of the injured persons. With a view to showing the consequences of accidents taken as a group, in this respect, these are classified according to the "extent" and "degree of disability." The main classification by the extent of disability was discussed above in connection with accident severity. The "degree of disability" is fixed according to different criteria in different groups of disabilities. In fatal cases it is indicated by the age of the killed person; moreover, these cases are classified by the number of his dependents. Non-fatal cases resulting in "permanent disability" are often classified according to the percentage of incapacity for work, total disability (e.g., loss of both eyes) being taken as equal to 100. Cases of "temporary disability" which form about 94% of all accidents, are subdivided according to the number of working days lost. According to an estimate based on the statistics of a number of countries, this loss is in one-third of the cases less than a week; in two-thirds, less than a month; and in about 95% of cases, less than three months.

Finally, industrial accidents involve important financial consequences. The loss of earnings consequent upon industrial accidents affects in the first place the workers, but a part of this loss is, in practically all countries, a charge on the employers in virtue of workmen's compensation and accident insurance legislation; moreover, the State participates in many countries by bearing the cost of the administration of insurance institutions. International comparisons are still less feasible in this field than in other parts of accident statistics, and for several countries, e.g., the United States and France, no information is available. In Great Britain, the regular statistics only show a part of the cost; a recent official estimate, however, puts the total charge on employers in 1925 (including compensation, administrative expenses, commissions, profits, etc.) at £12,117,000. In Germany, the total of payments of the industry and of the State to the accident insurance institutions was in the same year RM. 266,916,000 (£12,934,000). And it should be remembered that these amounts represent hardly more than one-third to one-half of the aggregate burden which industrial accidents constitute on labour and industry as a whole.

PREVENTION OF ACCIDENTS IN AMERICA

The prevention of industrial accidents, or as it is popularly termed in the United States, "industrial safety work," is that activity undertaken by the employer or in some cases by groups of employers, to remove the physical causes of accidents and to encourage safe practices by the employees. Estimates show that between 23,000 and 25,000 persons meet their death annually as a result of industrial accidents, while approximately 3,250,000 receive non-fatal injuries from the same cause. The economic cost of accidents in industry is placed at \$1,000,000,000 annually. The industrial accident situation, therefore, presents a social problem of considerable importance, as well as a great economic problem.

To the employee an accident means the loss in income equal to the difference between his pre-accident wage and his accident compensation or the wage he is capable of earning after the injury. To the employer, accidents mean the expenditure of funds for the payment of compensation awards, medical and burial expenses or insurance premiums to cover the same. They also mean the permanent or temporary loss of valuable employees; the demoralization of the working force; damaged equipment, raw material and finished product; and curtailed production. These latter items, it has been computed, represent a charge equal to at least four times the cost of compensation and medical service or insurance premiums. To the general public, industrial accidents mean an increase in the cost of living, as the expenses of the manufacturer are included in the cost of producing his product.

In the early years of accident prevention work in industry, it was considered largely a duty of the mechanical engineer in designing and erecting guards and protective devices and making provision for the greater physical safety of the workman. In some cases such activities were required by State law. In other cases, encouragement was given by insurance carriers through their plan of offering credits on premiums. It soon became apparent, however, that human defects and failures were accountable for a much larger proportion of accidents than were mechanical defects. In 1928, statistics indicated that between 80 and 85% of all industrial accidents are due to unsafe practices, while only 15 to 20% are chargeable to unsafe conditions. Methodical education, therefore, is the governing principle in the prevention of industrial accidents.

A study of successful industrial accident prevention work shows that the best results have been obtained in organizations where safety activities, both mechanical and educational, are considered as a direct function of supervision, rather than as a welfare activity, independent of production. It has been the experience of many organizations that the degree of success resulting from the safety plans is dependent in large part upon the amount of direct personal interest taken in this phase of operation by the chief executive. To the employees and supervisors, he is representative of the company and his interests and activities reflect the policy of the employing organization. In the majority of larger plants or companies, however, the chief executive cannot give personal direction to this because of many other duties. In such cases it is customary to assign this work to some other official, sometimes with a supporting staff, to direct the safety activities. In some organizations the safety engineer is placed on the staff of the personnel director. Regardless of the type of organization, however, it is considered important that the individual in charge of safety be given a position on the company's staff, which

will clearly indicate the importance with which the employer views the safety work.

A system for obtaining reliable information relative to each accident and for tabulating and utilizing this material is considered essential to a reduction of the accident rate. It is customary to obtain an accident report from the injured employee's immediate superior. Where the nature of the injury is serious or the indicated cause of sufficient importance, this initial report may be supplemented by an investigation or by a hearing conducted by the safety director and a committee of workmen or supervisors. Accident statistics are usually classified by cause in order to determine their relative importance and to serve as a guide in planning for safety. This information also provides effective material for use in educational work. Based upon the accident statistics, the accident frequency rate (usually considered as the number of injuries per 1,000,000 man hours worked) and the accident severity rate (the number of days lost per 1,000 man hours worked) are developed to measure the effectiveness of the accident prevention programme and to serve as a means of comparing the progress and standing of the various units of the organization. Accident cost figures are frequently used to keep the executives informed of the value of the safety activities.

Within the individual unit of the industrial organization, the responsibility for the prevention of accidents is placed upon the respective supervisors—the superintendents or foremen. They are charged with carrying out the safety policies of the management, with the aid and advice of the safety engineer or director. Interest in this plan is sometimes secured by including safety as a definite part of staff meetings. Information regarding the company departmental accident experience and the causes of accidents are furnished the safety supervisors. Through personal contact, participation in meetings and general or personal letters from the chief executive, the safety policy of the company and the part which supervision has to play in it are kept before those in charge of others. In the final analysis, however, the cause and prevention of accidents rests with the individual employee. It is essential that the employee be selected and placed with due consideration to his physical and mental ability to perform his designated duties in a safe manner.

Safety Methods.—The general methods of accomplishing this are fairly well standardized in American industry to-day, although the details incident to carrying them out vary considerably. The outstanding methods are given below.

Department meetings provide an effective means of developing mutual interest in safety between foremen and men. These meetings are usually called and presided over by the foreman and present an opportunity for free discussion of the past accident experience of the group and of measures for the prevention of future accidents. Safety committees of foremen and men serve to place a definite responsibility upon the committee members. Through the rotation of membership the entire force may gradually be reached and convinced of the value of safety to the employee. Advertising through bulletin boards, special messages on blackboards, safety signs, pay roll inserts, leaflets or articles in house organs aids the management to keep the idea of safety constantly before the working force. Friendly competition between plant units, plants or companies provides a definite incentive for the practice of safety. Safety rallies or mass meetings of employees and their families arouse a group interest and encourage the formation of constructive public opinion. The introduction of safety education in the grade school curriculum helps to train the future workman and also provides a splendid medium for reaching the workman through his children.

Considerable aid in connection with industrial safety work is rendered to American industry by the National Safety Council, bureaux of the U.S. Government, State departments of labour, individual insurance companies, organizations of insurance companies, trade bodies and other national and local institutions. (See also *INDUSTRIAL WELFARE AND MEDICINE*; *SAFETY FIRST*; *DANGEROUS TRADES*.)

INDUSTRIAL ARBITRATION AND CONCILIATION: see *INDUSTRIAL RELATIONS*.

INDUSTRIAL ARCHITECTURE. This article is concerned with the design of contemporary buildings in which manufacture, purchase, sale, exchange or transport of commodities is carried on, or the financing of business enterprises is negotiated. Architecturally, it represents the most important developments of the early 20th century, which is primarily an age of industry. The number, mass and height of factories, office buildings, stores, etc., have increased, and their design has improved, more than could have been deemed possible at the close of the last century. The reader may also well consult the article *ARCHITECTURE*; a comprehensive list of related articles in this work appears under the heading *ARCHITECTURAL ARTICLES*.

I. INTRODUCTION

The birth of the industrial age towards the middle of the 19th century coincides with discovery of iron to be used for machinery and transport. Iron and industry, material for machinery and production by machinery, are implicit in each other. Their joint conception, namely the conception of "technique," was the symbol of a new age, of a new generation. That generation regarded industrialism as more or less their own creation, as some magnificent weapon forged for private use, as something national rather than international, fighting competitors both at home and abroad. There resulted from all this a sharp contrast between the lifeless monotony of their factories and the unproductive swagger of their administrative buildings and offices.

The World War marked the end of this first stage of development. The economic and social results of the war produced what was the beginning of a fundamental change of attitude. Industrialism began to be regarded in a clearer perspective and the essential principles of its activity to be recognized; that is, its cultural possibilities and the necessity of adjusting it to some world-embracing scheme. Hitherto science has regarded the two conceptions, material and energy, as separate from each other; we recognize to-day that they are merely different conditions of a single primary element. The modern engineer therefore is abandoning the old mechanistic theory of dead material and is again coming to believe in vitalism as the principle to which he is obliged to render service. Machinery, which till now has been the ready tool of a dead exploitation, is becoming the constructive element in a new and living organism. Machinery was born as a necessary by-product of development, and at the very moment when the need for it arose. The essential task of machinery is to satisfy, to co-ordinate, and to control the mutual relations between population and increased production, between industrialization and increased consumption of human material. In this way machinery can be regarded both as a symbol of overripe decay and as an element of a new life which is capable of ordering itself afresh.

Through the discovery of mechanical potentialities, men and cities, countries and continents have become directly inter-dependent. Each knows the other, each requires the other. This universalization of requirements is complete: never was fashion so internationally authoritative as to-day. Social distinctions are diminished, abolished; national distinctions wear each other away, cancel each other out; a supra-national point of view is formed; isolated particularities, the result of geography, climate and race, are merged in the whole. In this way the spirit of man is freed from the narrowness of the Middle Ages. No longer is the Earth a gloomy corridor, it is living reality, and a spiritual, as opposed to a material fulfillment. Reason and inspiration, the earthly and the heavenly, are at the same moment implicit in it. Thus the traditional conception of God is changed; belief and doctrine find a new basis in a conception which is at once broader and more universal than any hitherto known, and calculated to absorb those antitheses. Individualism and Collectivism, Capitalism and Socialism, divest them of their dogmatic character, and achieve a final compromise. The individual is the "first servant" of the general; the general is the basis on which leaders of men work. In other words, the new world-conception will only be shaped by a fusion of the dogmas of materialism and idealism.

As applied to the domain of architecture this realization means

that pure calculation and pure inspiration when considered alone are without roots, but by their fusion Industrialism is freeing itself from materialistic limitations. The gloomy and desolate factory of older days is becoming a temple of labour, a shrine of creative reality. This affective revolution must, if it is sincere, express itself in form, and in convincing form. It coincides with the revolutionary discovery of new material for construction, of iron and reinforced concrete. The new methods of construction are leading to a revolution in the whole practice of architecture, since the application to building of iron construction with its scientific principles and its static calculus is supplanting the traditional theory of construction on the load and support principle by the principle of hinged construction of the girders. The first iron girder represented a solution of an architectural problem no less important than that by which the middle ages replaced the classic formula by the invention of vaulting. But for centuries the human eye has been accustomed to deduce the solidity of a building from the harmony of its horizontal and vertical constituents. It is thus obvious that we are making some demand on human comprehension, and one which can only gradually be satisfied, when we ask people to transfer their sense of statics from the traditional principle of load and support to the architectural methods employed in iron construction. The first architectural experiments with rolled iron date back to the middle of the 19th century, to that amazing production, the Crystal Palace in London.

Structural technique, and architectural expression simultaneously achieved a common basis when the World War enormously increased industrial production both quantitatively and qualitatively. We are to-day on our guard against wastage of human labour even as we avoid the wastage of material which was inseparable from the older methods. We rationalize a man's capacity for work even as we rationalize our bricks and mortar. They are both so much raw material. We render building an industrial production, we render the craft of building an industry of building. We thereby eliminate the contradiction between human efficiency and machine work by regarding both as a law of material and ideal self-preservation. Only by such means can the way be opened for a homogeneous form, by which the logic of our new materials can be uniformly applied to industry, transport and building. Since the products of industry, owing to the clarity and precision of their shape, are the most authentic evidence of the new capacity for form, since our modern means of communication are the purest symbols of the spirit and pulse of the age, so also must industrial building, regarded as architectural production, draw its sustenance from the same soil as has given birth to the forms and shapes of technical production. Thus it is industrial construction which is leading the way towards a new style of architecture. It was industrialism that invented, or, more correctly, necessitated, our new material: it was industrialism also that called into being the means and localities of production. It is industrialism therefore which has imposed on the craft of building its definitive tasks, from the first primitive workshop up to the large factory of the modern industrial corporation. Industrialism has thus progressed beyond its original material aims, and has become at once the womb and the nurse of a new development which will carry us over from the death of the civilization of the 19th century to the emergence of a fresh form of creative culture. This development is based upon a uniform material need and upon a uniform spiritual attitude. It is supra-national and already carries with it as its symbol the elements of a new conception of style.

(E. MEN.)

II. INDUSTRIAL BUILDINGS

It was not until the World War that architects and engineers had given to this class of building any special study and the outcome of their efforts has resulted in increased production and better working conditions for the operatives. An increase in the interest in factories from the international standpoint has accrued by the fact that a great number of firms are setting up factories in countries to which they are foreign. This building abroad has been caused by the duties levied on imported articles and has had

a tendency to make the industrial building a very standardized structure.

Whilst it is not possible to lay down rules applicable to all countries because building work is always governed by local restrictions such as climatic conditions, materials, national characteristics and resources, industrial buildings may be divided into two classes, the one-storey building and the multi-storey building. Most large factories embody in their sequence of manufacture both these types, the heavy components being allocated to the one-storey buildings, and the lighter to the multi-storey. For foundries, forge shops, heat treating plants and plants manufacturing articles producing in the course of their creation noxious odours, the one-storey is employed. Where ground is cheap and large areas are available for future expansion of business the modern practice, especially in the United States, is to use the single storey building throughout the entire sequence of manufacture, both for the making of light and heavy articles. This method is ideal for mass production and would be extensively used were it not for insufficient available ground area and the relative extra cost of the single storey building over the multi-storey building per square foot of floor area.

The multi-storey building is usually constructed of either steel or reinforced concrete and is designed so that extra floors may be added with the increase of business. The usefulness of this class of building has been greatly enhanced by the introduction of the continuous conveyor system as the floors are now no longer dependent upon an elevator service for vertical transportation of goods during manufacture. The multi-storey building is restricted in width by lighting and ventilation requirements which in turn are relative to an economical height from floor to floor. This ratio of width to height of floor varies little in all countries and the majority of multi-storey buildings are designed so that the glass in the side walls is not less than 22% of the floor area. The height, floor to floor, is usually between 12 and 14 ft. and the width of floor area from 50 ft. to 90 ft. The area of ventilators should not be less than 30% to 35% of the total area of the windows. In South Africa and in other countries with similar intensity of light the area of glass must of necessity be reduced to one-third of that used in European buildings and no direct sunlight must be allowed to enter.

In order to gain a maximum of light and ventilation use has been made of an elevation with a continuous window. This has been made possible by using a cantilever construction so that no columns are visible on the exterior. It is this type of construction which has given to the multi-storey factory a façade which lends itself to an expression suitable for an industrial building; by its great scope has been given to the architect in his endeavour to uplift its aesthetic qualities. The most satisfactory attempt in dealing with this problem has been to encase the whole elevation with a large architrave of flat bands sometimes enriched with coloured tiles or faience work; this has the effect of giving stability to the strong horizontal lines of the continuous fenestration.

One-Storey Buildings.—Where one-storey buildings are necessary the practice in Europe is to use the north light type of factory, the usual pitch of the roof being 60 and 30 with the horizontal (see Plate, fig. 9). These roofs are designed so that no direct sunlight can enter the building and by this method a uniform intensity of light is distributed throughout the building. The height from floor to supporting beam is usually from 12 to 15 ft. but where a great deal of overhead shafting is used the height is increased to obtain an adequate drive for the belting. A modern tendency is to localize power units, and a growing tendency in favour of individual motors for each machine permits the height of the one-storey building to be reduced. This is an asset which, so long as the ventilation is adequate, makes construction and heating requirements less expensive.

For certain manufactures in America north light factory roofing is considered obsolete. This form of construction has given way to a variety of a new combination of trusses which give better lighting and ventilation and are sometimes known as the "butterfly" truss (see Plate, fig. 7). Apart from the improvement in the efficiency of a factory and its workpeople, this butterfly con-

struction possesses many qualities which will give the industrial architect opportunities for making the single storey factory building just as complete a piece of architecture as the multi-storey factory has now become. Hitherto the multi-storey building stood alone in having gained for itself a definite style of architecture.

The outstanding demand of the modern manufacturer is for clear floor space and this demand is fully met by this construction. Spans from 50 to 60 ft. are usually more necessary in the one-storey building than the multi-storey building and whilst these can be obtained by north light construction, butterfly construction solves the problem more efficiently for certain manufactures. North light with its awkward angles makes maintenance work expensive whereas in butterfly construction, flashings, ridges and surface water problems are considerably reduced. The interior appearance of a one-storey building designed with a butterfly truss is superior to the north light type and receives readily the numerous factory accessories such as sprinklers and heating pipes. In order that the direction from which the light enters the building may be always changing throughout the day, these roofs are faced east and west. Tests have been made and it has been proved that operatives suffer less fatigue when the object upon which they are working has varying intensities of light cast upon it. The direct beam of light is diffused by the use of prismatic or ribbed glass so that this variation may be kept within working limits. There are articles which will not withstand this alteration of light values, but the majority of manufactures are not affected by even a very strong light for short periods during their production. An excellent natural ventilation is brought about and is controlled by automatic opening gear, consisting in some factories of ranges of glass over 800 ft. which are operated by one push-button, the entire length of glass moving en masse. Whilst this is recommended in certain cases 100 ft. is most preferred. With this type of roof facilities for cleaning the glass are much more convenient than with the north light construction, as the cleaner can work freely from the flat portion of the roof.

Layouts.—Great strides have been made in the layout of works, and sequence of manufacture has become a special study in all countries. It is in this sequence of manufacture that mass production has been made possible. The elimination of handling and reduction of the travelling distance necessary for an article during its creation has been reduced to a minimum. Many large factories incorporate in their layout large service basements in which goods are conveyed from one part of the factory to another without covering any of the manufacturing area. These are also used as interim stores in which goods may be placed awaiting their despatch to another department. So important is this sequence of manufacture that it is among the first drawings prepared for a proposed new factory, and great care is taken to design the building in such a way that some or all departments may receive additional area without a dislocation of the normal sequence of manufacture. In America use is made of apartment factories in which several firms will rent floors in the same multi-storey building thereby greatly reducing the transport of goods when these manufacturers are inter-dependent.

The delivery and despatch of goods varies in the different countries; in the United States and on the continent of Europe much use is made of railway transport, even for the smaller factories; whereas in England considerable use is made of road transport and many important factories are found depending solely upon this method. Many factories are now independent units and it is possible in some instances for workpeople to obtain within their own works most of the necessities as well as some of the entertainments of life. It is not an unusual occurrence to find in America and in many European factories, large recreation grounds, ranges of shops, hospitals, restaurants at which the employees are supplied at cheap rates. The two main considerations in modern factory design are the possible maximum output and the health and welfare of the factory operatives, and there are architects and engineers who specialize in this branch of building. (See also **FACTORY DESIGN**.)

See *Internationale Architektur* (ed. W. Grotius, Munich, 1925); W. Linder, *Bauten der Technik* (1927) and current architectural periodicals of London, New York, Paris and Berlin.

INDUSTRIAL BUILDINGS: INTERIORS

Interior Surfaces.—The interior surfaces of factory buildings are largely controlled by the manufacturer and there are many ways of treating wall surfaces, ceilings and floors. A granolithic concrete surface has been found satisfactory, and is used extensively in England. Maple and woods offering similar properties are also used, but the surface of floors has not come so near perfection as other materials in factory work.

All excrescences and ledges on wall surfaces are reduced to an absolute minimum. Generally the wall surfaces are painted in a light colour; in corridors and passages they should always receive a dado of a darker colour at least shoulder-height. The actual wall surface is best left in concrete and all edges protected with metal casings where liable to be in contact with trucking. The floors of lavatories should be laid to falls, and the walls tiled.

The divisioning of a factory should generally be reduced to a minimum. Where it is essential the division walls should take the form of metal-glazed removable screens so that in the event of any future alteration they may be taken down and re-used without interference either to themselves or floor and walls to which they were attached.

Ceilings of both one-storey and multi-storey buildings should act as reflecting surfaces and should be designed so that they may be easily cleaned and are not liable to condensation.

Miscellaneous Buildings.—There are many structures complementary to the purely industrial or manufacturing make-up of any large centre of commercial production; e.g., warehouses, silos, gate houses, railway sidings, chimney stacks, power stations, reservoirs, markets, coal bunkers, fire stations, water towers, etc. These structures are necessary adjuncts to the factory proper, but they may form units by themselves.

When they are part of the factory group, the location of these smaller dependent units may form part of the sequence of manufacture. They should be placed so as to function with the factory and incidentally they themselves must be capable of further extension. It is in these structures that the industrial architect is given the opportunity to create a layout that not only allows the most efficient manufacturing process, but also gives relief and contrast in building shapes.

The warehouse, usually a large multi-storey building of low floor heights and small window area, is in direct contrast with the airy and light feeling of the manufacturing plant.

The chimney stack, always a dominating feature, need not be looked upon as something to be rid of, for if in itself it is well designed it can serve a useful purpose, to mark the main axis.

Many water towers have been designed in reinforced concrete and treated frankly as such. Others have been erected in structural steelwork and both of these types have their merits but the latter has to be studied very carefully in order to produce an effect which will be in sympathy with the rest of the group of buildings.

Independent Structures.—When these complementary buildings are independent structures they must be designed from another aspect and are usually on a much larger scale. The warehouse, and more especially the grain elevator and market, are buildings which sometimes dominate all surrounding architecture. There are many examples of silos, towering structures in concrete, whose mass effect is one of the finest achievements in modern architecture. Grain elevators, in which huge quantities of grain are stored, weighed and shipped need not be the ungainly structures which they are occasionally. An example of well designed silos is that at Capetown Harbour where a large grain elevator gives a scale and fits well into the background afforded by Table Mountain.

The enormous height of the grain elevator is mainly due to the fact that the thrust of the grain is constant and it is therefore economic design to carry these structures to a great height. In addition to these huge structures, small silos are found alongside the railroads in agricultural districts of the grain producing countries for ensiling the produce of the local centres.

Markets.—In recent times there have been a few new examples of that old institution, the market, which is now chiefly

used for the sale of perishable goods. The advent of the large store buildings has been a deterrent to their extended use, and so it is only in a few cases where a large self contained market has been a practical proposition. The huge factories which now deal in perishable manufactures have also restricted the extension of the market system. But there are examples such as T. Garnier's market at Lyons which is in itself an industrial group and has skillfully combated the problem of dealing with a large floating population.

(D. T. W.)

III. COMMERCIAL BUILDINGS

Under this heading are included all buildings designed for the purchase, sale, exchange or transport of goods or for the work involved in the financing of businesses, etc. In former times the bulk of business was carried on between individuals and their more or less immediate neighbours; when the business concerns, then comparatively small, built at all it was for themselves; 40 years ago a small building or one or two floors in a larger one sufficed. The corporation, the trust and the super-trust have since been organized. To-day nearly all business is national in scope, and much of it international; it requires great headquarters in the principal cities, notably the larger ones, and sky-scrapers in concentrated masses, grouped for centralized business as in New York, co-ordinate and speed it up. Business has either to build for itself on a vast scale or else to rent space in the buildings now being erected with a rapidity heretofore unequalled (*see ARCHITECTURE*). Building space is produced where it is needed and where speculating builders think it will be; it is manufactured, rented, sold; it differs from other merchantable commodities only in that it cannot be transported; but for this reason, and because considerable capital is necessary for any building and full returns on the investment may not come in for years, speculation in this field is small.

The need for larger buildings and the introduction of skeleton construction, two factors that appeared almost simultaneously, have resulted in the new American architecture whose buildings have tremendous bases and multi-storeyed towers (*see ARCHITECTURE*). To preserve adequate light and air for all, however, in most American cities the form of the new buildings is restricted by law, with a tower of unlimited height sometimes permitted on an area equal to one-fourth of the lot (*see ZONING*). Aesthetically, the most refined effect and greatest symmetry, and practically, the best lighting and ventilation, are obtainable when this tower rises from the centre of the lot, a position in which it can also be taller and structurally stronger than when placed elsewhere.

OFFICE PLANNING

Since the office building of the sky-scraper type is the most distinctive example of commercial architecture, let us consider it in detail. The usual procedure in most plan studies is to start with the ground floor and build up. But in planning office buildings, and this applies to apartments and hotels as well (*see SOCIAL ARCHITECTURE*), the architect reverses this process and plans from the top down. That is to say, he develops a typical upper-floor plan first, because the major income is derived from these typical floors, and if some sacrifice is to be made, it can better be made on the ground floor than on the office floors. A typical office unit is first determined upon, a series of such units is arranged along both sides of a corridor, and then the line of vertical circulation (lifts or elevators) is fixed at a central point on this corridor so that no tenant is obliged to walk more than 100 ft. from his office door to an elevator. Utility spaces—toilets, cleaners' closets, vent shafts, flues, etc.—are then added and the plan is completed. A type of plan which, with the ever-increasing concentration of business and the development of larger and larger organizations, is rapidly becoming popular, is that in which a building is designed as a solid mass, as opposed to the more usual type in which it contains area-ways and courts. The typical upper-floor plan of such buildings shows a series of connecting offices on the outside, while the artificially lighted and ventilated core of the building is given over to elevators and rooms for storage, conferences, etc., belonging in common to the occupants of the various offices. This type necessitates each floor being occupied by a complete organiza-

tion, or at least members of the same profession, and in New York, for example, the installation of common services, notably for doctors, in whole buildings occupied by them, has been carried even further to include rooms for special examinations, appliances and even attendants.

Authorities differ as to what constitutes the ideal office unit; they agree that it is better to have less space (less capital investment) permanently rented at a high figure than much space partially rented at a low figure. Lighting is the important factor here. The depth, *i.e.*, distance from windows to corridor, of a well-lighted office is never more than twice the clear ceiling height. Twenty feet is better than twenty-five. The width of the unit varies with the distance between steel columns, which economical engineering consideration places at not less than 15 ft. nor more than 22 feet. In the best office units each internal division can be subdivided into smaller rooms in the single large office unit. Although a 4 ft. corridor might serve all practical purposes, the width should increase with the length for the sake of beauty of proportion. Corridors should also increase in size as they approach the elevators.

The building lot at the architect's disposal determines the arrangement of offices. It should be noted that "dark" spots, such as always occur where a wing joins the main building, are used, as far as possible, for the necessary utilities, such as elevators, stairways and smoke towers. Toilets can be artificially ventilated and lighted, but it seems better to place them on small back courts, which furnish inferior office space at best, thereby retaining some degree of natural light and full natural ventilation. The British building laws require outside toilets, always; *i.e.*, they must always have outside windows, no matter how much artificial ventilation may be provided.

Staircases and Elevators.—In American office buildings, stairways are little more than fire-escapes. As the law requires them to be entirely enclosed with fire-resisting walls and doors, they are never conspicuous and rarely visible. In London, where the height of buildings is limited to nine or at the most ten storeys, there is one conspicuous open stairway and there are one or two sets of enclosed stairs.

Elevators are often the key to the plan scheme and are usually grouped together for greater service efficiency. Even small buildings have at least two (because of possible breakdown), and if more are needed on account of greater floor area or greater number of storeys, they are so placed that a tenant waiting for a lift may be able to step easily to the first one that flashes a signal. A battery of six elevators, three facing three, is the ideal arrangement. Eight, four facing four, are possible. More than eight in one battery is not practical, because then the passenger might not reach the lift before it had passed. If more than one system is installed, the systems must be separated enough for each to serve effectively an entirely new area, and the plan problem simply repeats itself; *i.e.*, two buildings side by side, but with connecting corridors.

Just as 100 ft. each way from the elevator line is the convenient limit one may go horizontally, 15 storeys is about the limit of effective service for a single battery. As the building with ground area for one group of elevators increases in height, it may require a battery of more than eight, in which case the problem becomes two buildings, one placed on top of the other, with the vertical circulation of the upper structure running through the lower as an "express" service.

Lighting.—Window spacing and height is an important consideration. The usual bay between steel columns is from 15 to 20 feet. Experience seems to dictate the use of two windows in this bay. One window to a bay gives too much wall space and too little light; three windows give too little wall space and too much light. An even field of equally spaced windows is more elastic for interior division into offices. The amount of natural light is not as important as the quality of light. Windows located with regard to exterior architectural effect rather than to interior comfort and convenience sometimes extend nearly to the floor, while above is left a dark void of wall space and ceiling. Many windows of average size are preferable to a few large openings, just as several

well-distributed ceiling lights in a room give better illumination than one powerful centre light. In most northern countries, particularly North America, window openings have to be suitable for both tropical summers and severe winters; while large glass surfaces are attractive in warm weather, they cause financial loss in the heating of buildings and discomfort in cold.

Ground Floors and Basements.—No general principles can be formulated for the planning of ground floors, basements and sub-basements, because conditions vary widely according to the local problem. In the entrance hall, in addition to the elevators, telephone booths, news-stands, etc., specialty shops of all kinds and frequently a bank occupy the spaces opening on the streets. The entrance hall itself is often lavishly adorned; magnificent and imposing entrances are appreciated by the tenants and facilitate the renting of space. The ceilings are often treated in colour; the metal-work on the doors, elevators and mail chutes is sometimes masterfully conceived and executed; large lamps made up of vertical and horizontal planes of coloured glass hang from the ceiling; an effect of spaciousness is striven for. Straight lines and simplicity in the various designs introduce an air of modernism.

The number of floors below the street level depends on the height and, to some extent, on the location of the building. Some very high buildings have as many as five floors below the street level. In some, situated near subway stations, tunnels run from the building to the station; the first basement floor then becomes a second entrance hall; however, it is usually simply treated and such services as boot-black stands and extra telephones are installed. Caretakers' quarters, boilers and other mechanical equipment are located on various of these subterranean floors according to the needs of the problem.

Theory and Forecast.—A business city is essentially a manufacturing plant producing everything from architectural plans to legal briefs. It is created with a full service of streets and buildings but is used to full capacity hardly eight hours a day with Sundays off. The plant works at 30% efficiency. Cities have never been intelligently planned because they have never been planned co-operatively. Individual buildings have been well designed from the point of view of distinct units, but never from the point of view of the community as a whole. There is a tendency in building to utilize larger and larger lots. In New York city, for example, the Telephone building and the New York Life Insurance Company building both occupy small city squares. If the city square were made the lot unit for a building, it would be possible to design structures to serve better the various needs of modern city life, with each building a coherent part of the whole scheme. Buildings so planned could contain apartment dwellings in the top storeys and commercial spaces in the lower; a man leaving his office could then take an elevator to his home; the enormous waste entailed at present when practically whole city populations are transported to and from their places of business twice daily would be eliminated. The cores of such buildings would be given over to elevators, communal services and theatres, elements in which artificial light and ventilation suffice. By using an arcaded side-walk one storey up with bridges at the cross streets the present side-walks could be given over to vehicles and the capacity of the present streets increased. Farther up, at the first set-back, above which would be residences, would be a second side-walk, as a promenade. The other set-backs could be used for terraces and gardens. Business and residence would be united, economy effected and an abundance of light and air provided for the dwellings. On the ground floor, on a level with the vehicular traffic, could be supply services, motors, power and electricity, while underground would be parking spaces, and, further down, sewerage.

When a building occupies an entire city square, it requires four distinct lines of distributing elevators instead of one or two. It becomes four buildings instead of one; *i.e.*, four similar units with connecting corridors. It might be possible to provide means of transporting people through buildings in some way other than or additional to the present system of elevators. None has yet been tried. There has been no building large enough. A large city square, 200 ft. by 800 ft., generally faces two avenues of which one

is more important. While in a building occupying such a square several entrances would be placed along the side streets and both avenues, a starting point for distribution might be determined at a point near the most important avenue. A moving stair or similar contrivance might be developed to carry passengers toward the rear and sides of the building while rising. This would probably serve only the first 10 or 12 storeys, as, owing to the narrow side streets, most building laws permit an average of only about 12 storeys, with a tower on an area equal to one-fourth of the base. Due to the size of the average city squares, buildings more than 200 ft. wide from the elevator centre are improbable.

The architectural treatment of a building for advertising purposes is receiving increasing consideration. The Telephone Company and Sears Roebuck and Company are but two examples in the United States that, each having their own architects, give their buildings throughout the country a distinctive appearance. In the American Radiator building, New York city, Raymond Hood has portrayed in the black shaft and the gold and red crest the glow and warmth of heating apparatus. Such advertising features, used as an inherent part of a building's composition, have aesthetic as well as commercial value. The time is coming when crude signs will be considered as offensive as foul smells; restrictions on noise, smells and ugliness will increase as the aesthetic sense of the public is educated.

The illumination of the exteriors of buildings at night will, probably, play an important part in the city architecture of the future. Already flood-lights are used on the upper set-backs to illuminate the topmost storeys. With the development of new materials and the ever-improving methods of lighting, it is possible that the giant buildings of future cities will be beacons that light both directly and by reflection the streets themselves.

BANK BUILDINGS

The planning of modern banks and financial institutions involves the many mechanical improvements that affect lighting, ventilation and control, and the new inter-communicating devices that facilitate the rapid transaction of business. Due largely to experiments made by the Federal Reserve System of the United States, established by act of Dec. 23, 1913, vault construction has made notable advances, certain types of vault being virtually impregnable to fire, burglar and even mob attack. Although these practical matters are part of the architect's work, they do not materially affect the aesthetic problem. One tendency that does concern the purely architectural aspect should be noted. The main banking room, where the major part of the public transacts business, is becoming more and more the architectural feature of the interior. Even the officers of the bank, from the president down, are quartered in this space, and the various partitions necessary to separate bank employees and public take the form of screens, counters, rails, etc., which thereby become a kind of furniture rather than an architectural separation. Some of these great banking rooms are among the most magnificent and richly treated spaces in modern architecture, comparable to the interiors of government buildings (*see* GOVERNMENTAL ARCHITECTURE), or those of the palaces of former times.

The period when it was considered necessary for banks to be designed like Greek temples has passed, and their most characteristic exterior feature to-day is an air of solidity and permanence. They frequently occupy part or all of the ground floor in office buildings, but where a whole building is constructed for one, the exterior (through few windows and wide expanses of smooth wall and imposing metal ornament) is designed to give an effect of impregnability and endurance. Iron, especially since the invention of non-rustable iron alloys, has been used increasingly in grilles, for it has inherent decorative qualities as well as the appearance of strength. The vault is usually placed in the basement, for it is more easily protected there, and, according to the psychology of safety, it is a better advertising feature for it to be situated underground than on the main floor where it is conspicuous to every passer-by. Among large banks it is becoming customary for the same architects to design all the branches, giving them a characteristic style; their common qualities, however,

are usually achieved through decoration, since the dissimilarity in lot sizes and building shapes makes it difficult to get much similarity in exterior design.

STORES

Following the trend of all commercial and industrial construction, stores are being concentrated in larger units. The small shop on the street level continues to exist, and, the modern designers of its façade, in both Europe and America, in their efforts to attract the passer-by, have taken full advantage of new materials, combinations of colours and tastes in composition (*see SHOP FRONT DESIGN*). The great department store is the principal modern solution of the retailing problem. The building often covers an entire city block (occasionally even two), and is sometimes many storeys in height. By means of quantity purchase and elaborately developed service and delivery systems, the department store supplies the public with every kind of commodity, so competing with the specialty shops. In its design the architect must consider (1) the movement of people, and (2) the movement of merchandise.

In Paris and Berlin the centrally lighted "well" type of store, with its surrounding galleries, is still the rule and gives an impressive interior which is both airy and attractive. But in London and New York every inch of floor-space is utilized, and artificial illumination takes the place of the natural light proceeding from the sky-light over the central well. In fact, American building laws in most cities do not permit the open well form of store because of fire hazard. In addition to the usual lifts, the movement of shoppers is facilitated by means of mechanical devices such as escalators and ramps. Intercommunicating belt conveyors, etc., are usually installed to speed the movement of merchandise.

TRANSPORT

Although architecture relating to transport is here listed in the commercial category, transport affects every branch of human endeavour more or less directly and might well be discussed under any or all subdivisions of contemporary architecture.

Railway Terminals.—This is the most important problem the architect has to deal with in this group. Mammoth stations are becoming an impressive feature of the modern city and, since the advent of electricity has largely eliminated the old-fashioned smoke-filled shed that architects formerly tried to express, they offer fine opportunities for architectural genius. There are two reasons: the tendency to combine the terminals of several railways in a central or union depot, and the increasing realization that railway stations are the real gateways of the modern city. Moreover, business communities grow up around railway stations, property values increase, and the terminal may then take the form of a sky-scraper with income producing offices in its upper storeys. Hotels adjacent to, and even connected with, the terminal are, of course, frequent. First impressions are likely to be lasting ones, and no better point could be chosen at which to make an effective display. Even in small towns and villages, stations are being erected in keeping with the local environment and designed with an eye to artistic fitness. Generally speaking, two classes of people make use of a station; those travelling daily to adjacent suburbs, who know precisely where and how to go, and desire to reach their trains with the least possible inconvenience; and strangers who must make inquiries at every turn. The architect, therefore, has to provide an entrance of generous proportions leading directly to a central hall where information booths, booking-offices, luggage-rooms, parcel deposits, news-stands, etc., are convenient, and from which gates to trains, conspicuously marked, are readily accessible. Furthermore, the movement of trains, luggage and freight involves engineering complications of no mean order. These exacting requirements have been met with notable success in several imposing structures. The Pennsylvania station (McKim, Mead and White, architects), and the Grand Central terminal (Warren and Wetmore, architects), both in New York, the Union station in Washington, D.C. (D. H. Burnham and Company, architects), the new Union station in Chicago (Graham, Anderson, Probst and White, architects), and the station at Helsingfors, Finland (Eliel Saarinen, architect), are some of the most impressive examples. (*See RAILROAD PASSENGER TERMINALS.*)

Airports.—The growing popularity of air transport has cast a new challenge to the architect. International air travel is an accepted fact on the continent of Europe to-day, and its air terminals require all the passenger facilities of railway stations plus the customs provisions of steamship docks. At the airport of the future passengers will doubtless be able to take different lines to different countries and transfer from one line to another. Future airports will be centres of international as well as domestic travel; the boundaries of a country will no longer mark its ports of foreign call. Since the first requisite of an airport is a good flying field, it is usually situated outside the city that it serves; consequently hotel and restaurant facilities must be provided for both passengers and pilots, and subway or bus terminals for the lines transporting people to and from the field.

The architectural development of the airport is in its infancy. For the most part flying fields have been equipped merely with mechanical requisites, and planned mainly from an engineering viewpoint. With the present rapid growth of the industry, however, the possibilities afforded for designing airports with imposing and striking effect, making use of the most recent methods of construction and lighting, and the need for these new entrances to nations and cities to be impressively planned is becoming appreciated.

Perhaps the most striking design at the present time is that planned by Maurice Chauchon for Pau, France, 50 m. from Bordeaux, which is considered a strategic site for airway travel. The international aerodrome, 370 ft. wide by 260 ft. long, will hold three giant commercial continental passenger planes, the wing-spread of each being about 130 feet. The plan is conceived in such a way that the hangars can be made longer and more added when necessary. Parts of aeroplanes and all mechanical supplies required will be kept on hand in adjoining machine shops. The project calls for a restaurant, hotel, customs-house, information bureau, ticket office, money change booth with provisions for the exchange of foreign money, porters, radio and meteorological service. A roof of glass slabs set in reinforced concrete provides daylight illumination for the main hangar. At night, at either side of the aerodrome, two lateral beams can be deflected over the ground to indicate the best angles for landing, according to the direction of the wind; two vertical beams, each of 1,000,000 candle power, are especially adapted for foggy weather; a permanent light will always be displayed in the right-hand corner of the field; the name PAU, in illuminated letters 70 ft. long, will be so sunk in the ground that planes can taxi over it safely.

(H. W. C.)

INDUSTRIAL ARTICLES. The various aspects of industry, its development and ramifications are fully dealt with either in key articles or under separate headings, while in the separate articles devoted to the great industries themselves will be found historical introductions of those industries together with indications of the general linking up of modern industry.

The following branches of the study of industrial conditions are treated under special headings, viz:—

ASSOCIATIONS, INDUSTRIAL; ELECTRIFICATION OF INDUSTRY; FATIGUE IN INDUSTRY; INDUSTRIAL ACCIDENTS; INDUSTRIAL COUNCILS; INDUSTRIAL COURT; INDUSTRIAL FATIGUE RESEARCH BOARD; INDUSTRIAL INSURANCE; INDUSTRIAL PSYCHOLOGY; INDUSTRIAL RELATIONS; INDUSTRIAL REVOLUTION; INDUSTRIAL TRANSFERENCE; INDUSTRIAL WELFARE AND MEDICINE; INDUSTRIAL WORKERS OF THE WORLD; and NATIONAL WORKSHOPS. A special article, INDUSTRY AND TRADE, WAR CONTROL OF, embodies the chief industrial lessons learned from the World War.

Labour's increasing activities in coming to grips with organized industry are well-covered in the various articles on LABOUR and its connotations. Labour colonies are found treated in the article FARM COLONY, and other leading articles of interest to students of labour and its problems are LABOUR DAY; EMPLOYMENT EXCHANGE; HOURS OF LABOUR; STRIKES AND LOCK-OUTS; TRADE UNIONS; TRADE UNION CONGRESS; TRADE, WORLD'S STATISTICS, and kindred articles such as TRUSTS and TRADE ORGANIZATION.

All the main articles are supplied with full cross-references to subsidiary articles where further and, in some cases, more detailed

information will be found.

INDUSTRIAL ASSOCIATIONS: see ASSOCIATIONS, INDUSTRIAL.

INDUSTRIAL CHEMISTRY may be broadly defined as applied chemistry, whether in testing laboratories or in chemical industry. Recent compilations by the National Research Council indicate more than 1,000 industrial research laboratories in America, and to these should be added laboratories which analyse materials against specifications, exercise control over some industrial processes, and examine finished products with reference to published guarantees or the purchasers' stated requirements. The recognition of adequate analysis and testing has spread to department store and individual laboratories as well as to corporation and Federal Government laboratories. The interpretation of analytical results is usually more important than the data themselves. Even the older industries such as baking, ceramics and textile manufacture now recognize the necessity of chemical control as a major step in plant efficiency, cost reduction, waste elimination and uniform properties of saleable products. Many industries not commonly regarded as chemical industries are successful only when under complete chemical control. The manufacture of sugar, tanning of the best leather, and the manufacture of steel are examples.

Remarkable strides have been made in the chemical industry since 1914, when the World War made necessary the rapid creation of such an industry to supply the shortage of many necessities, particularly in the field of organic chemistry. This situation confronted England, America, France, Italy, Japan and practically all civilized countries, since Germany had specialized in this type of manufacture and exercised a virtual world monopoly. As a result, many countries determined to become self-contained so far as the chemical industry was concerned, providing in particular chemical compounds such as synthetic pharmaceuticals, medicinals and dyes which, though comparatively small in tonnage, bear such relation to other industries as to give them the character of a "key" material. The end of the World War saw a world supply far in excess of the demand for many types of industrial chemicals. There followed a number of drastic readjustments. Many of the smaller manufacturers had to discontinue and sell out to their financially stronger associates, or unite themselves in groups. The laws and customs of the different countries have directed this readjustment to a great extent. In Europe cartels have been formed. The most important example is the *Interessengemeinschaft* or "I.G." of Germany, which has become a cartel of international importance, with connections reaching into not only all major lines of chemical industry but into allied fields, particularly those concerned with raw materials. Consolidations have taken place in Great Britain, giving rise to Imperial Chemical Industries, Ltd., an exceedingly strong group composed of the major chemical manufacturers of Great Britain. There have been international agreements on the European continent with respect to division of market, consolidation of sales and advertising, and similar functions. In the United States there have also been certain groupings or consolidations, but due to the Sherman Anti-Trust law, there has been nothing approaching the I.G. in extent.

NEW INDUSTRIES

Chemistry has introduced many new notes into industry. The photographic industry is an example of one founded on a single chemical fact, namely, that halogen salts of silver turn dark in the light. Unpromising raw materials have been made the basis of new industries such as the manufacture of ethylene glycol and its derivatives from natural gas, and the preparation of amyl alcohol and compounds derived therefrom, from pentane separated from natural gas gasoline. Cellulose derived from wood, cotton and annual growing stocks, has been made the promising raw material of the immediate future, and already supplies a variety of lacquers, several kinds of artificial silk or rayon, artificial leathers, sausage casings and films used for a variety of display and wrapping purposes. Synthetic resins, prepared in the laboratory, have provided a building material of great importance in these days of mass production, lending themselves particularly to

moulding compounds, enabling metal inserts to be moulded in place, and intricate forms to be produced by a single operation. Acetic acid, once a by-product of wood distillation, is now produced by fermentation, and acetic anhydride is prepared by catalysis from acetylene gas. Methanol is prepared on a great scale from gases derived from coal. Aluminium since its introduction into industry has become a metal of many uses produced in great quantity. Metals such as tungsten, tantalum and molybdenum, once regarded as rare, are now important commercially. Another service has been the supply of materials prepared according to precise requirements. The range of alloys permits to-day a careful selection, depending upon the peculiar use, thus contributing directly to economic savings possible through longer life in service or resistance to rust and corrosion.

In the field of organic chemistry the work of arranging atoms and molecules to order has been of the greatest importance. The organic chemist begins by isolating and identifying the active principle of some natural medicinal product. When the characteristics of such a compound have become established, he then proceeds to synthesis. This work begins in the laboratory and when perfected there, goes through semi-works development and innumerable physiological tests before manufacture is attempted on a commercial basis. By this method it has at times been possible to eliminate groups of atoms found to be responsible for such deleterious properties as habit-forming, or perhaps other groups are added in the synthetic product to widen the use of the compound or make it more specific. Such work does not always start with natural products, for organic chemistry now produces in commercial quantities numbers of compounds quite different from anything known in nature and devised to meet a particular need.

Chemistry is valued by industry on many accounts. It serves to guard raw materials as to quality and supplements them by establishing new sources. It prevents waste by assisting in the selection of materials for particular uses, thereby avoiding the production of "seconds." It turns by-products into profits and often creates a new industry as a result. It speeds production by the improvement of processes and by imparting improved physical characteristics through changes in chemical composition. It protects the guarantee by determining in advance that the warranted material will meet specifications. It supplies reliable information as to products and processes as well as trends in industry; such information may save industry by avoiding surprise. It has assisted in breaking monopolies and in countless instances has reduced costs to a surprising degree. Since chemistry is a fundamental science dealing with the ways of materials, it naturally occupies a position in the front rank of the aids to modern industry. (H. E. H.)

INDUSTRIAL COUNCILS. In the principal British industries working conditions in the widest sense—including wages, hours of labour and terms of employment generally—are normally settled or adjusted by some form of direct negotiation between employers organised in associations and workpeople organised in trade unions. As between these organisations there has been built up, in many industries, more especially those engaged in the export trade, stable and definite machinery for discussion often comprising elaborate local and national arrangements for conciliation and for arbitration in the last resort. Thus the half century prior to the World War witnessed, side by side with the growth of representative associations formed for contest, the joint development by these organisations of conciliation or arbitration machinery for avoiding disputes or settling them if they arose. A Royal Commission appointed in 1891 drew attention to the existence and spread of these voluntary conciliation boards and urged their extension and encouragement. In 1911 an attempt was made by the State to strengthen the machinery of conciliation by the establishment of an Industrial Council of a national character, comprised of 13 representatives of employers and a corresponding number of workpeople and presided over by a nominated independent chairman, "for the purpose of considering and enquiring into matters referred to them affecting trade disputes, and especially of taking suitable action in regard to any dispute referred to them, affecting the principal trades of the country as

likely to cause disagreement involving ancillary trades, if the parties before or after the breaking out of a dispute are themselves unable to settle." The Industrial Council of 1911 functioned for a time, but in the special circumstances created by the war it fell into abeyance. Since the war the extensive voluntary machinery for direct discussion between organised employers and workpeople has been supplemented by the creation of Joint Industrial Councils formed in accordance with the recommendations of the Whitley committee of 1917.

See also INDUSTRIAL RELATIONS, CONCILIATION AND ARBITRATION, WHITLEY COUNCILS, STRIKES AND LOCKOUTS. (J. H.)

INDUSTRIAL COURT. The Industrial Court is a permanent Court of Industrial Arbitration to which the British Minister of Labour can refer, with the consent of both parties, industrial disputes for settlement. The Court had its origin in the recommendations of the Whitley committee (report of 1918) which were in part to the effect that there should be established a standing arbitration council to which differences might be submitted in cases where the parties failed to reach an agreement and wished to refer to arbitration. Effect was given to these recommendations in the Industrial Courts Act, 1919. Under Part I. of this act a trade dispute may be reported to the minister of labour, whereupon the minister has to take the matter into consideration and to take such steps as seem to him expedient for the settlement thereof. This enables the minister, if the parties to the dispute consent, to endeavour to settle the dispute by conciliation. The fact that such action is taken only by the consent of the parties ensures that negotiations are carried on under favourable conditions; and it is by conciliation that the majority of disputes in which the minister is called upon to intervene are settled, in many cases by the ultimate agreement of the parties to refer their difference to arbitration. An important provision of the act (section 2 [4]) is designed to ensure that, before a difference can be referred to arbitration, any existing joint conciliation or arbitration machinery shall have been tried and found wanting. The arbitration procedure outlined in the act is that the minister of labour may, with the consent of the parties, refer differences to arbitration either by the Industrial Court, a single arbitrator, or a board of arbitration constituted of employers and workpeople with an independent chairman. During 1927 there were issued 82 decisions on cases referred to the Court for determination, making a total of 1,354 decisions since the establishment of the Court. In Part II. of the Industrial Courts Act the minister is given power to enquire into the causes and circumstances of a dispute, whether apprehended or existing, and if he thinks fit, to refer any matters appearing to him to be connected with or relevant to the dispute to a Court of Inquiry. This power is intended to be exercised by the Minister in cases in which, in his opinion, the interests of the public are involved and the object is to render the public familiar with the authentic facts of the dispute. A Court of Inquiry is not a form of arbitration, and there is no question of securing the consent of the disputants to its appointment. Courts of Inquiry have power to request persons to give evidence and, though no penalties are attached to failure to fulfil the request, in no case has it been refused. Up to the end of 1927 sixteen Courts of Inquiry had been appointed.

See Reports of the Ministry of Labour for years 1923 and 1924 (Cmd. 2,481) and for 1927 (Cmd. 3,090). (J. H.)

INDUSTRIAL ELECTRIFICATION: see ELECTRIFICATION OF INDUSTRY.

INDUSTRIAL FATIGUE RESEARCH BOARD, a body constituted in 1918 in Great Britain under the control of the Medical Research Council to study, on scientific lines, problems relating to the human factor in industry. It is responsible for a special series of published reports. (See FATIGUE IN INDUSTRY; and INDUSTRIAL PSYCHOLOGY.)

INDUSTRIAL INSURANCE. The system of industrial insurance in its present form has been evolved from the endeavours on the part of small local burial societies to secure to persons in humble circumstances a sum sufficient to defray their funeral expenses. Many of these small societies are still in existence, but as it became apparent that there was a general demand for the

services which they rendered, other organizations founded on a broader basis, and employing the medium of collectors, were established, and have developed to such a degree that the business now transacted by the larger collecting societies and industrial insurance companies has attained enormous proportions. The provision of funeral benefits remains the predominant function of the system. The advantages of life insurance as a means of making provision for dependents are, however, becoming more generally appreciated. The great majority of the contracts in force consist of whole-life policies, but the popularity of endowment assurance, which is so conspicuous a feature of ordinary life insurance business, appears to be extending in some measure to industrial insurance.

The principal characteristics of the system are well known, and all, or at least some of them, are present in a greater or less degree in every form of industrial insurance policy: the sums assured are small in amount, the premiums are collected by agents at the homes of the assured, and are generally payable weekly or at other short intervals, and the weekly premium is the basic unit of the tables, the sum assured being the variable depending upon the age of the policyholder and the form of policy. It is interesting to note that the statutory definitions of industrial insurance have varied in different countries, and even from time to time in the same country according as emphasis is laid on one or other of these characteristics.

In Great Britain industrial assurance business is defined by the Industrial Assurance Act, 1923, as that of effecting assurances upon human life, premiums in respect of which are received by means of collectors, and are payable at intervals of less than two months. In the same Act a collector is described as a person who makes house-to-house visits for the purpose of receiving life assurance premiums.

The British System.—An account of the British system may serve to indicate the essential principles governing the conduct of industrial insurance business wherever it may be transacted.

In Great Britain industrial assurance business is regulated mainly by the Industrial Assurance Act, 1923, 13 and 14 Geo. 5, c. 8. The institutions authorized to transact the business of industrial assurance are divided into two classes, registered friendly societies, referred to in the Act as collecting societies, and assurance companies, referred to in the Act as industrial assurance companies. The operations of registered friendly societies are governed by the Friendly Societies Acts, and those of assurance companies by the Assurance Companies Act, 1909, and the provisions of these Acts so far as they have not been superseded or repealed by the 1923 Act continue to apply to societies and companies transacting industrial assurance business. Under the Act the Chief Registrar of Friendly Societies is constituted the sole authority for the supervision of industrial assurance business, and in this capacity is to be known as, and styled, the Industrial Assurance Commissioner. The powers conferred upon the commissioner include not only those in relation to industrial assurance business hitherto vested in the Board of Trade and the Chief Registrar of Friendly Societies respectively, but also certain others of a far-reaching character. He may reject any account, return a balance sheet that does not comply with the requirements of the Act, and give such directions as he thinks necessary for the variation thereof. Disputes may be referred to him, and acting in a judicial capacity he may hear and determine such cases. He has power to investigate offences, and in cases where he has reasonable cause to believe that an offence has been committed or is likely to be committed, he is authorized to hold an inspection into the affairs of the society or company. His decisions in the more important cases are published in the annual report which he is required to make each year of his proceedings under the Act, and which is to be laid before Parliament. By the 1923 Act every company and society transacting industrial insurance business is required to deposit and to keep deposited with the Paymaster General in respect of such business the sum of £20,000.

Under the Life Assurance Act, 1774, a policy issued to one person on the life of another is invalid unless the person proposing the assurance has an insurable interest. By the 1923

Act and the Friendly Societies Act 1924, policies insuring money to be paid for the funeral expenses of a parent, child, grandparent, grandchild, brother or sister are not to be invalidated by the absence of insurable interest. The maximum sums payable on the death of a child are, however, fixed at £6 for children under three years of age, £10 for children up to six years of age, and £15 for children up to ten years of age.

The provisions of the Act relating to valuations are of great importance. The valuation must be made by an actuary, and the basis is to be such as to place a proper value on the liabilities, regard being had to the mortality experience, to the average rate of interest from investments and to the expenses of management including commission. There is in the Act no suggestion of anything in the nature of a standard basis of valuation or of a maximum scale of expenditure on management. A certificate is to be given by the same persons as sign the balance sheet that the assets are in the aggregate fully of the value stated therein. The commissioner has power to reject a valuation, and order it to be amended, and may direct further particulars and explanations to be furnished in order to satisfy himself whether the valuation complies with the provisions of the Act. If a valuation discloses a deficiency the commissioner may, if he is satisfied that the society or company should cease to carry on business, take the necessary steps to have it wound up.

Lapsed Policies.—The large number of lapsed policies has been a frequent subject of complaint in regard to industrial insurance business. The Act, however, contains stringent provisions for safeguarding the rights of owners of policies. Before the forfeiture of a policy can be incurred, a notice of the arrears owing must be served and 28 days allowed in which to pay. If the arrears are not paid, and the policy has been in force for a prescribed period, the owner of the policy is on making application to the insuring office within one year from the date of the notice, entitled to a free paid-up policy or in certain circumstances to a surrender value. Rules are prescribed for ascertaining the value of a policy and for determining the amount of the free paid-up policy. The provisions regarding forfeiture are to be printed in every premium receipt book.

The Industrial Assurance Act, 1923, was the direct outcome of the recommendations of a departmental committee appointed in 1919 by the Board of Trade to enquire into the business carried on by industrial assurance companies and collecting societies. The committee in the following year presented a unanimous report criticizing the methods of some of the offices, and proposing amending legislation.

COLLECTING

Costly Collections.—The great problem which all industrial insurance companies, no matter where they may be established, have to solve is the reduction of expenditure. The collection of premiums by agents is necessarily a costly process, and owing to the smallness of the sums involved, the expense ratio must inevitably be considerably higher than in the case of ordinary life assurance business. Most companies are able to conduct their ordinary business at a cost of about 12 to 15% of the premiums, but from the evidence furnished to the departmental committee it appeared that the average annual total expenditure of companies and societies on industrial business for the six years 1912-17 represented about 44% of the premium income. In 1926 the expense ratio for all companies had fallen to 34% and for all societies to 41%. The former of these two ratios is weighted heavily by the experience of the largest company whose rate of expenditure has shown a progressive decline to 26%, a figure which is much lower than that of any other company. The substitution of a salary basis of remuneration for that of commission is becoming more usual, and the introduction of the "Block system," under which a given area is exclusively allotted to a particular agent, promises to be productive of satisfactory results.

The tables issued by industrial assurance companies usually show for each age at entry the sum assured by weekly premiums of one penny or multiples thereof. The plan of taking the penny premium as the unit facilitates accounting as well as collection by

agents. There is an increasing tendency, however, especially in the case of endowment assurances, to quote the sums assured by monthly premiums, and as in ordinary assurance business to show the premiums required to provide specified sums assured. The following are specimen rates taken from the prospectus of a large British office:—The sum assured at death by a premium of one penny per week is, for age next birthday at entry 10, £15:0:0; age 20, £10 18s.; age 30, £7 17s.; age 40, £5 7s.; age 50, £3 9s.; age 60, £2 3s. A premium of 5s. paid every four weeks will secure at the expiration of 15 years or at death, if previous, for age at entry 1, £45; age 10, £44 5s.; age 20, £43 5s.; age 30, £42 10s.; age 40, £40 15s.; and age 50, £37 10s.

In Great Britain, since 1919, almost all offices have issued revised tables giving more favourable terms than formerly. This has been made possible by the general decrease in the death-rate, and the increase in the rate of interest obtainable on investments. It may be anticipated that with the continuance of these influences, profits will enure, to a share of which policyholders will no doubt be admitted, even although industrial insurance policies usually do not carry the right of participation in profits. Several offices, both proprietary and mutual, have for some time had bonus schemes in operation, and surpluses have been distributed either in the form of additions to the sum assured or curtailment of the period for which premiums were originally payable. One large company for many years gave "mortuary" bonuses, that is, additions to the sum assured varying with the duration of the policies, in all cases becoming claims during the ensuing year or a further specified period, but to policies issued since Jan. 1, 1923, a vested bonus conditional only on the policy remaining in force for five years is allotted in respect of the premiums paid in each year. This is a reversionary bonus, payable at the same time as the original sum assured, thus introducing into industrial assurance business a system of distribution of surplus previously confined to ordinary business. In the last year for which information is available this company distributed to its industrial policyholders surplus amounting to not far short of £3 millions. Another large proprietary company has extended to existing policyholders the advantages of the new tables intended for future entrants, under which larger benefits are insured. These concessions to industrial policyholders are examples of the general disposition on the part of directors and proprietors to admit them to a share in the prosperity of the company. It must be pointed out, however, that the first task confronting a number of offices has been to strengthen their reserves to the standard required by the 1923 Act.

The publication of the first complete return of the results of valuations under the British 1923 Act affords an opportunity of surveying the position of British Industrial Assurance organizations. The date of valuation in the majority of the cases was Dec. 31, 1926. The following is a summary of the results:—

British Industrial Insurance Returns

	Industrial assurance companies	Collecting societies	Total
No. of companies or societies	18	170	188
No. of policies	56,097,000	15,529,000	71,626,000
Sums assured	£821,542,000	£202,951,000	£1,024,493,000
Assurance funds	£164,688,000	£32,634,000	£197,322,000
Surpluses	£6,589,000	£1,935,000	£8,524,000
Deficiencies	£53,000	£357,000	£410,000

From an analysis of the returns it can be affirmed that there has been a definite strengthening of the bases of valuation, that the proportion of expenses to the premium income is diminishing, and that a general improvement in the administration of the business in the interests of the policyholders is being effected. The proportion of the surpluses to the sums assured appears to be greater for the societies than for the companies, but this is attributable to the fact that the companies' surpluses are in most cases the results of annual valuations, whilst those of the societies have accumulated during the longer intervals which had in many instances elapsed since the previous valuations.

It will be observed that the number of policies brought under review was nearly 72 millions, about two policies per head of the total industrial population of the British Isles, assuring on the average about £14 each.

The total funds held by the companies and societies amounted to about £200 millions, a notable result of the accumulation of a multitude of small sums contributed by a large proportion of the total population, who are thus given a direct interest in the financial stability of the nation.

Statistics of Growth.—The stages in the remarkable development of industrial assurance business are indicated by the following statistics.

In Great Britain, for industrial assurance companies and collecting societies together, in 1877 the premium income amounted to about £2 millions, in 1897 it was about £9½ millions, in 1907 about £17 millions, in 1920 nearly £36 millions, in 1925 £45,182,000, and in 1926, the latest year for which figures are available, £45,435,000. At the end of these years the funds amounted to nearly £2 millions, £21½ millions, £48 millions, £108 millions, £184 millions and £201 millions respectively. In 1926, 8,116,000 policies were issued, a decrease of about a quarter of a million from the average of the previous five years which was attributable to the coal strike.

In Australia the number of policies in force at the end of 1925 was 1,311,000, or 220 policies per 1,000 of population, and the sums assured were not far short of £50 millions.

These are impressive figures and indicate that industrial assurance is performing a very valuable social service. It is claimed, and no doubt quite reasonably, by the advocates of the system, that such results could not be obtained without the personal contact of agent and policyholder.

It is clear, however, that the agents do not restrict their activities to industrial business but use the opportunities afforded by their acquaintance with the circumstances of policyholders to advocate the advantages of the extended benefits to be obtained through the medium of ordinary life assurance. That these efforts are attended by considerable success is evidenced by the fact that both in Great Britain and in America the largest industrial offices transact also the largest amount of ordinary business. The practice of using the organization of the industrial branch to extend the operations of the ordinary branch is no doubt profitable to the offices and their agents, but they are entitled to claim that it enables them to confer on their policyholders the benefits of assurance facilities at the relatively cheaper rates of the ordinary system. Amongst other examples of the pressure deliberately exerted by offices in popularizing the less expensive types of policy may be mentioned the recent development of industrial assurance by monthly premiums.

(P. G. B.)

UNITED STATES AND CANADA

Industrial life insurance in the United States and Canada is, in general, similar to that transacted by the British insurance companies. The collecting societies, however, have no counterpart here. In the United States, supervision of industrial as well as other insurance is exercised not by the Federal Government, but by the several States. In Canada the business is regulated partly by the Dominion Government and partly by the provinces. There are few States that have specifically defined industrial insurance, although often references in the law indicate its nature. The following definition was adopted in New York State in 1927: "Industrial life insurance is hereby defined to be that form of life insurance, either (a) under which the premiums are payable weekly, or (b) under which the premiums are payable monthly or oftener, if the face amount of insurance provided in the policy is less than \$1,000, and the words, 'industrial policy' are printed upon the policy as a part of the descriptive matter." In Canada, the Dominion Insurance Act, as amended in 1927, provides, "industrial insurance" means life insurance the premiums for which are payable at shorter intervals than quarterly and are normally collected at the home of the insured."

Early History and Growth.—Prior to 1875 insurance for workingmen and their families was supplied largely by co-opera-

tive societies, which frequently failed after a comparatively short existence. There were also arrangements whereby social organizations collected premiums weekly and paid them over to insurance companies. During the year 1875, through the efforts of John F. Dryden, the Prudential Friendly Society was organized in Newark, N.J., and in 1877 the name was changed to the Prudential Insurance Company of America. This company adopted in large measure the methods of the Prudential of London, and may properly be called the first industrial company in America. In 1879, the Metropolitan Life and the John Hancock of Boston, both of which were already transacting ordinary insurance, commenced writing industrial insurance. These three companies now have in force over 85% of the industrial life insurance in the United States.

The business was introduced in Canada in 1881, and is now carried on there by three Canadian, two United States and an Australian company.

Industrial insurance has grown steadily and rapidly in volume and in public favour. Policy conditions have been greatly liberalized, and restrictive provisions in the earlier policies gradually eliminated. Expense rates and lapse rates have been notably reduced, and mortality rates, especially at the younger ages, have greatly improved. Hence the companies have been able to largely increase the amount of benefit for a given premium. As an illustration, in one company, under a policy issued in 1895 on a child aged two years next birthday, weekly premium ten cents, the maximum benefit, reached after 11 years, was \$230, whereas under the present table, the benefit for the same weekly premium is \$424, reached in nine years, and the premiums cease at age 75. The remarkable growth of this form of insurance will be seen from the following table (*Spectator Year Book*, 1927) showing the industrial insurance in force in United States companies:—

End of year	Policies in force	Insurance in force
1880	228,357	\$ 19,590,780
1900	11,215,531	1,468,474,534
1920	49,178,887	7,121,380,255
1926	78,268,739	14,213,136,743

The foregoing table includes the business of United States companies in Canada, amounting in 1926 to 3,217,885 policies and \$517,984,522 insurance. It also includes not only policies of pure life insurance, but policies of combined life, health and accident insurance. Some of the small companies are not included in the tabulation.

At the end of 1927, there were probably more than 100 companies transacting industrial life insurance in the United States, most of them issuing only life insurance policies, but some, especially in the South, issuing policies of combined life, health and accident insurance. It is estimated that these companies had in force in the United States at the end of 1927 about 76,000,000 policies of pure life insurance, representing perhaps 45 or 50 million lives, and \$14,500,000,000 insurance, about 7% being on coloured persons. In addition, there were probably 3 or 4 million policies of combined life, health and accident insurance carrying 200 or 300 million dollars of life insurance, and weekly sickness benefit of many millions. In Canada, at the end of 1927, there were about 3,900,000 industrial life insurance policies in force, with insurance of \$680,000,000.

Plans.—Most industrial life insurance is based upon the collection of a weekly premium of 5 cents or multiples thereof, with the amount of insurance varying according to the age at entry. Many companies also publish tables for even amounts, such as \$100 and \$250, with the weekly premium varying according to age. While premiums are usually payable weekly, the Metropolitan Life Insurance Company has also been issuing monthly premium industrial policies, at reduced premiums, since the beginning of 1927. The most popular industrial policies are whole life (frequently with premiums ceasing at the age of 70 or 75) and 20 year endowment. In most companies, insurance may be written at any time from birth up to age 60, 65 or 70 at entry. The average benefit per policy is about \$200, but the average amount

per insured person is larger because many persons carry two or more policies. Policies are rarely written for more than \$1,000 except by the principal Canadian company, which issues a special series of weekly premium industrial policies at reduced premium rates, for \$1,000, \$1,500 and \$2,000. The benefits on policies issued on children usually start considerably below the maximum provided under the policy, and increase with duration until the maximum is reached. Several States, in fact, and the principal Canadian provinces, limit the insurance a parent may legally carry on the life of a child. From about 1895 to 1905, there was considerable agitation against the insurance of children, but this movement has gradually become of little importance.

Bases.—The mortality table in most common use for the calculation of reserves is the Standard Industrial Table, based on the experience of the Metropolitan Life on standard industrial risks during the period 1896–1905. It has been recognized as a permissive standard by laws of New York State and Canada. The more recent tables of premiums and benefits, however, have been based, directly or indirectly, on later and much improved mortality rates. Mortality under industrial policies is naturally much higher than under ordinary policies because of the lower economic status of the average industrial policy holder. The interest rate generally assumed for calculation of premiums and reserves is $3\frac{1}{2}\%$.

PRACTICAL WORKING

Collections.—A company usually divides its territory into "districts"—a district being a part or the whole of a city, perhaps with nearby cities and towns. It is in charge of a manager or superintendent, controlling a staff of agents, together with assistant managers or assistant superintendents averaging about one for every eight or nine agents. The agent is usually compensated partly by collection salary or commission, based on the size of his "debit" (i.e., the business on which he collects), and partly by a commission for his "increase" in weekly premium, resulting from the excess of new business issued over business lapsed. Industrial agents, as a rule, write ordinary insurance as well, and are paid a commission thereon. There are not far from 70,000 industrial agents and probably 10,000 managers, superintendents and assistants. By far the greater part of industrial insurance is written without medical examination, being inspected by the writing agent.

Policy Provisions.—Industrial policies are usually incontestable after one or two years from the date of issue. There may or may not be a named beneficiary, but in either event, most policies contain a "facility of payment" clause permitting payment to any relative by blood or connection by marriage or other person incurring burial or other expenses on behalf of the insured. Restrictions as to travel or residence are rare, and in the large companies there is no limitation of benefits on account of suicide. There is usually a grace period of four weeks for payment of premiums—in monthly premium policies it is 31 days. Reinstatement of lapsed policies within one year, upon satisfactory evidence of insurability, is usually provided by the policy, and actual practice is still more liberal; in two of the large companies, revival is permitted within 13 and 20 weeks respectively, irrespective of the condition of health. If premiums cannot be paid in cash, many companies will reinstate lapsed policies by charging the arrears against the policy as an interest bearing lien. Non-forfeiture values in the form of extended insurance or reduced paid-up insurance are usually provided after payment of premiums for three (sometimes five) years. Cash surrender values are usually granted after ten years; in some companies five. There is seldom a provision for loan values. One large company provides that if premiums are paid for one year direct to the home office or a district office, thereby saving the expense of collection by an agent, a refund of 10% will be allowed the policy holder. The John Hancock Company has always been a mutual company, and the Metropolitan and Prudential companies were mutualized in 1915. Dividend distribution is annual, and the dividends to industrial policy holders declared by these three companies in 1927 amounted to approximately \$79,000,000. Dividends are declared mainly in the form of credits on premiums, paid-up additions to the face of the policy, and mortuary and maturity dividends, which are addi-

tions to death claims and matured endowments. Most of the small companies are stock companies, and pay no dividends to policyholders. The London Life of Canada, although a stock company, allows mortuary and maturity dividends. Disability benefits and double indemnity in case of accidental death, such as are common in ordinary insurance, are rarely found in industrial policies. Some companies, however, including the largest three, do provide a disability benefit payable in event of total loss of sight, or the loss of both hands or both feet, or one hand and one foot; in a few companies, also for the loss of a single hand or foot.

Health and Welfare Work.—The weekly calls of the agents at policy holders' homes afford the companies a notable opportunity for health and welfare work. Among their activities are the dissemination of health literature, offers of free nursing service, participation by the companies in general public health work (in co-operation with public health authorities), including surveys of sickness and unemployment, studies of mortality and sickness, health exhibits, health demonstrations in various localities, the exhibition of films, support of health legislation and publication of magazine advertisements relating to various phases of health and welfare. The Metropolitan company, which has been a leader in health activities, has in 19 years distributed about 490,000,000 pamphlets relating to health and citizenship, and has provided 30,000,000 free nursing visits to policy holders. The marked reduction in the mortality rate of its industrial policy holders—an even greater reduction than among the general population—indicates that its efforts have been successful. (R. V. C.)

INDUSTRIAL MANAGEMENT: see SCIENTIFIC MANAGEMENT.

INDUSTRIAL PENSIONS: see PENSIONS IN THE UNITED STATES.

INDUSTRIAL PSYCHOLOGY. Industrial psychology may be defined as the study of the conduct of men and women in their capacity as wage earners. It aims at describing and explaining all those activities by means of which a person adjusts himself to his economic environment; hence it must take into account the fundamental elements of man's constitution, his innate tendencies and their expression in thought, feeling and action both on the conscious and unconscious level, as well as his acquired aptitudes. As yet, only a tentative beginning has been made, so that we are far from even an approximation to scientific generalisation.

HISTORY OF THE SCIENCE

The development of industrial psychology has been largely determined by its history. Prior to 1914, psychologists concerned themselves but little with industrial problems. A few writers occasionally saw a possible industrial application of some psychological generalisation; and in 1913 Münsterberg made a more ambitious attempt (*Psychology and Industrial Efficiency*). Industrial development had been governed by the claims of machinery rather than of man. The enormous improvement in machinery during the 19th century, the studies made in the natural sciences, the growing knowledge of the mechanism of the body, all tended to focus general interest on man's likeness to a machine. The phrase "the human machine," which is rightly applied to part of his structure, became synonymous with man himself rather by implication than by design. The outbreak of the World War, with its urgent demands for increased production in all departments of activity, brought home to society the futility of considering the worker merely as a machine.

Industrial operations, as usually conducted, had been implicitly based on a crude mathematics. If 6 units of work could be done in one hour, then 6×8 would be done in 8 hours, 6×12 in 12 hours. The physiological necessity for sleep prevented the complete working out of this principle. Up to about 6 or 7 hours, according to the nature of the work, there seemed nothing obviously wrong with the calculation; when however, the problem was one of 12 hours, the discrepancy between the facts and the calculation challenged investigation. Though it was not then recognised, that stage marked an epoch in the history both of psychology and of industry. The focus of interest was changed from the machine to the worker of the machine, and the assistance

of psychology, hitherto looked upon as a somewhat recondite study, was invoked.

The Work Curve.—Previous work of a more or less theoretical character into problems of fatigue suggested the lines of investigation. Hence the earliest work in industrial psychology was concerned with fatigue. As the time was one of urgency, the problem had to be dealt with practically, and the only measure

FROM "INDUSTRIAL FATIGUE RESEARCH BOARD REPORTS"

GRAPH SHOWING INCREASE IN OUTPUT AND DIMINUTION OF ERRORS (BOTH TOTAL AND TURNED LETTERS) WITH INCREASE OF ILLUMINATION

to hand was the one that had prompted the inquiry, viz., the work curve, obtained by computing and graphing the hourly output records of numbers of workers. The reproach is sometimes made against industrial psychology that it is primarily interested in output. The truth is that output happens to be a convenient measure. Psychology's real interest lies in what is measured.

Hours of Work.—Thus the earliest systematic inquiries of industrial psychology concerned the problem of the 12-hour day in munition factories, and used as data the records of large numbers of people working over long periods. Comparisons were made between groups of people working a 12-hour day and other comparable groups working a 10-hour day. (*Health of Munition Workers' Committee*, [a] *Interim Report*, Cd., 8511 [1917]; [b] *Final Report*, Cd. 9065 [1918].) In many processes the results of the latter groups showed that an increase in hourly output more than counterbalanced the shorter time available for production, so that the total production was actually greater than when the hours of work were longer. Similarly lost time and sickness were found to diminish with the shorter working day. When hours are shortened, a long period elapses before adaptation to the new conditions is fully obtained; on the other hand, when hours are lengthened, there is sometimes an immediate reduction in hourly output.

Since the War, researches along these lines have been pursued in such different occupations as: charging of blast furnaces, silk weaving, shell making, metal-polishing, tinplate manufacture and in the processes of collar machining, folding and shirt ironing in the laundry trade. The curves of the output of the average worker, when graphed, usually assume the same general shape, viz., a rise at the beginning of the spell, a period of relative stability, and a fall at the end. The interpretation of these empirical facts cannot yet be given. Slight variations occur according to the arrangement of the hours of work, but the type remains characteristic of many industrial processes. Muscio, experimenting on women medical students doing mental tests, obtained similar curves.

Rest Pauses.—An important innovation stressed by the industrial psychologist has been the introduction of short rests, in the middle of a working period, of about 10 or 15 min. duration. These regular breaks are technically known as rest pauses. It is sometimes argued that frequent irregular rests are invariably taken by the workers, either voluntarily or because the supply of work fails, and that regular rest pauses are therefore not re-

quired. Where, however, direct experiment has been possible, it has shown that the organised rest pause is the better working arrangement.

The observations of H. M. Vernon for the Health of Munition Workers' Committee proved the advantage of breaking up working spells, and since then it has been verified in the boot industry, in metal-polishing, in celluloid-polishing, in shirt ironing, in sweet-packing, in handkerchief-folding and in stamping lids. The introduction of a rest about the middle of the spell of work improves the output as a rule by about 5%, and in some processes it affects advantageously the period preceding the rest. Not only is the work improved, but the regular rest is much appreciated by the worker. The probability is that the improvement is largely due to changes in feeling; most people can face with equanimity and possibly enthusiasm the prospect of two hours' work at the end of which will come a period of free time, but to face four or five hours of unbroken labour is depressing.

The subject of rest pauses has not yet been exhaustively studied, and particular cases need particular study; still the above statements seem to be valid in general. Exactly when a rest pause should occur must depend on the nature of the work, while the amount of actual increase in output will vary with the relation of the human factor to the machine factor in the particular process.

Physical Environment.—Among other influences that have been shown similarly to affect the worker and have been effectively measured by means of the output curve are improvements in lighting, heating, ventilation and seating. (See *FACTORY AND WORKSHOPS LAW*; *OFFICE MANAGEMENT*.)

MOTION AND TIME STUDY

At an early stage the young science of industrial psychology had to encounter the previous application of quasi-scientific methods to industry, initiated in America by Taylor and Gilbreth. Their general object was to study the nature and rate of the movements made by a worker, in order to eliminate the unnecessary ones. This is technically known as motion and time study. Unfortunately this study had resulted in imposing on all the so-called "one best way," obtained by analysing the movements of the quickest workers. So unnatural a procedure awakened much criticism and no little resentment. It is not irrelevant to note that the movement originated with engineers, not with psychologists.

Properly conducted, motion and time study are but special applications to industrial processes of the laws of habit formation. Young learners pick up, by watching proficient, many actions of industry; with practice they evolve a commendable copy but uncritically they may adopt some unnecessary movements which, while apparently not interfering with the work, may become fixed; the result is that the worker develops muscular habits

FROM "INDUSTRIAL FATIGUE RESEARCH BOARD REPORTS"

THE PATH TRAVELLED BY THE WORKER'S HAND IN ORIGINAL METHOD OF SWEET-DIPPING

harmful to himself, or fails to attain a speed commensurate with his real ability. Just as the skater, swimmer or golfer improves by expert teaching, itself the resultant of careful study, so does the industrial worker. In such varying trades as silk weaving, metal-polishing, chocolate covering, it has been found that by systematising movements and by training novices in the relevant motions, a saving of energy results, which is an advantage to all concerned. Faulty methods of learning are not only a hindrance during the learning period, but there is also an invariable tendency for the worker to regress to them under certain conditions, even when they are apparently overcome. (*The Medical Problems of Flying*, Medical Research Council Report No. 53 [1920] and *A Study of Telegraphists' Cramp*, Industrial Fatigue Research Board, Report No. 43.)

The aim of Taylor and Gilbreth, in standardising the time and method taken to perform a task, was primarily to reduce the cost

of production, and they also had in mind the welfare of the worker and higher wages. From the worker's point of view however, the drawback of their system was that it produced a feeling of being always keyed-up. From the psycho-physiological point of view it was based on the fallacy that the shortest and speediest movements were necessarily the least tiring, and that the best style of movement could be obtained from combining a number of best movements adopted by different workers. If the study of industrial processes in relation to the worker is to be scientific, it must consider the whole of the conditions, not a part; it must regard the worker as a human being, not as the performer of a limited set of movements.

LEADERSHIP AND MONOTONY

Important though the material environment undoubtedly is, no workers can do their best unless the general mental environment is right. Not even the very best material conditions will result mechanically in good work, and sometimes even poor material conditions can be nullified by good mental conditions. By this is understood the conditions governing the group as a whole, dependent primarily on the efficiency or otherwise of its leadership. Industrial life is often criticised for failing to supply that effective stimulus of working for a common end, which is more obviously evident in the army. Factories where there is this sense of working for a common end as well as for individual wages are more common than those not familiar with the inside working of factories realise.

If, as McDougall asserts (*The Group Mind*, p. 135 [1920]), "the personalities of its leaders more effectively than any other factor engender national unity and bring it to a high pitch," it is no less true that a factory owes its corporate unity to the personality of its leader and his deputies. The time may come when it will be possible to test for leadership as it now is for intelligence; at the moment the problem has only been formulated. The qualities of leadership are required by all those in charge of others, and there is no correlation between ability to do a job and ability to superintend others doing it. To the psychologist there

standing as to justify their position, then they need as emotional interpreter someone of different temperament to neutralise their more harmful effects.

A good leader should possess vitality, sympathy, justice and humour, as well as knowledge of the work. The emotional, and as a corollary, the physical effect on subordinates of different types of leaders is patent throughout industry. Where the commands of one are cheerfully obeyed, those of another arouse truculent antagonism or sullen acquiescence. Can anyone doubt the effect on the health, happiness and efficiency of the workers? Many authorities are unwittingly the cause of the sick leave they deplore among their subordinates.

Monotony.—In addition to the effect of the leadership, one has to accept the fact that in modern industry, with its subdivision of labour, a large number of people are employed in repeating the same limited set of movements for hours, days, months and years. This "repetition of movement" is often erroneously called monotony. Literally "monotonous" means "of one tone"; it suggests absence of change and refers rightly to the general mental atmosphere and not to the movements of the worker. Repetitive movements must either be studied as such, in which case they belong to the psychology of habit formation, or else put in their complete setting, including, at least, the repetition work, the varying amount done as the hours go on, the opinions of fellow workers and authorities about that work, physiological changes, emotional changes, and the collective life of the factory. The total reaction at any given moment will be the reaction to a composite situation which constantly changes.

The worker on one process often stigmatises some other process as monotonous, when to the observer there is nothing to choose between them. There are compensations too in many processes if one studies the worker as a human being and not merely as the performer of a repetition process; e.g., some workers experience a sense of power in operating a large or a delicate machine. It is not suggested that repetition work is good in itself; but merely to describe the repetition work as monotonous and to imply that such description embraces the whole psychological situation, is misleading.

VOCATIONAL GUIDANCE AND SELECTION

Observation of workers shows that in particular posts some are much more successful both subjectively and objectively than others. Hence arises the question of vocational guidance, which

DIAGRAM ILLUSTRATING DIFFERENT METHODS OF CARRYING

Investigation showed that these modes can be arranged in order of efficiency, the displacement of the body necessary to bring the centre of gravity over the foot being an important factor. Modes 7 and 3, yoke and bundle carrying, are most economical

are certain types, almost neurotic, whose symptoms find expression chiefly in their relations with others. The person who reacts always to the emotion aroused in himself by a situation and not to the situation itself, the inevitable "nagger" who can never govern easily because he is always at war with himself, the "obsessional" whose obsession can be readily touched up by the work—these represent a few whose emotional development makes life much harder for some of their subordinates and unbearable for others. (See M. Culpin, *The Nervous Patient*, p. 92 [1924].) If their other qualities, e.g., their business acumen, are so out-

must be distinguished from vocational selection, a simpler problem. The latter problem sets out to select a worker to fit the job, the former to select for a given person (usually an adolescent) that job most suited to his capacities. This theoretically presupposes a knowledge of the person, a knowledge of all possible occupations, and a power of relating one to the other. Those who have done most work in this field are convinced that the most useful measure of a person is his general intelligence.

Mental Ratio.—By suitable tests it is possible to gauge with a high degree of accuracy the intelligence of any child, and to ex-

press it in a quantitative form, known as the mental ratio. This remains fairly uniform throughout the years of growth, and inborn intelligence does not develop to an appreciable extent beyond the age of puberty. It is the amount and kind of knowledge and interests that separate the adult from the child, not the intelligence with which he deals with that knowledge and those interests. To put a child of a high level of intelligence to a job requiring little, is wasteful, while the reverse process is futile; moreover, the one provokes discontent, the other worry.

Temperament and Character.—In other directions, viz., the measurement of temperamental and character qualities, less advance has been made. In this field, observation and interpretation are still the only methods available. There are some occupations where people of a particular temperament are more likely to become inefficient and break down than in others. This temperament is characterised by a disproportionate development of fear in some form. Whether this is due to its innate strength or to some environmental influence, or both, cannot be adjudged yet. The sufferer shows over-anxiety concerning things he cannot alter, is unduly sensitive to the opinions of authorities, etc. Sometimes the symptoms appear in a more objective form, masking their actual subjectivity, so that the focus of anxiety appears outside the sufferer, who, with more than normal frequency complains of machine trouble, noise, unsuitable keys (in telegraphy), etc.

Such people, in the interests of themselves, their fellow-workers and the work, ought to be diverted from occupations where their mental make-up cannot fail to be expressed in the work. If they enter such occupations as telegraphy or dispensing or even coal-mining they will almost certainly break down: the breakdown will be attributed to overwork, although actually the overwork may have subjective rather than objective reality. If there is an occupational disease recognised as such, the problem is still further complicated. (*Reports of the Miners' Nystagmus Committee* [Medical Research Council Reports Nos. 65 and 80]; "Psycho-neurotic Aspects of Miners' Nystagmus" [*Brit. J. Med. Psy.* vol. iii. 1923].)

When the qualities of the applicant for a job have been assessed and the requirements of various trades are known, it is possible to advise a child as to what he may most advantageously take up.

Organization.—A vast field is, however, still untouched. Most of the studies made so far relate to those aspects of industry which are primarily a means to an end, not ends in themselves, and even in this limited sphere there is much to be done. Little is known as yet, for example, about the organiser and his organisation. It is obvious that the organisation of a big business is no mere rule-of-thumb working out of principles gained by even a scientific analysis of other places; it has some of the qualities of a work of art, and the attitude of mind of an original organiser is akin to that of the artist. No real appreciation of the field of industry is possible without a recognition of this.

INDUSTRIAL RELATIONS. This term is used to denote the relations of all those engaged in the production and distribution of goods and the rendering of services. It involves the methods by which the proceeds of these activities are divided between employers and workers or different classes of workers, and the settlement of the conditions under which work shall be carried on. The adjustment of the position of individuals in relation to those with whom they are associated in work is part of a wider adjustment in relation to the general community, and there is a close connection between political and industrial movements. In Great Britain the rapid development of the factory system during the Industrial Revolution and the concentration of the industrial

population in towns, largely destroyed the personal bond between master and man who had worked together in the scattered and rural hand industry units. The rapidity of the change and the domination of employers caused an embitterment of relations which has greatly influenced the labour movement.

Joint stock enterprise, which developed after the Limited Liability Act 1858, created a more complex situation than in the case of individual employers using their own capital, the employing section being divided into (a) investors of capital, (b) users of capital or management. The latter alone have relations with the wage-earners. The repeal of the Combination Laws 1824-25 gave workers the right to combine and to withhold labour by concerted action. Organization, hitherto confined to craftsmen, extended among other classes after a docks strike (1889). From 1910 the growth of trade union organization was shown by national and other strikes, one object of which was to secure the recognition by employers of the right of the unions to make agreements for their members in the industries concerned. During the War compulsory arbitration and State control of profits were instituted by the Munitions of War Acts. Results of the War were (1) increased trade union membership and political power; (2) the improvement of the earnings of unskilled and semi-skilled workers owing to (a) uniform cost-of-living advances without changes in base rates, (b) increased organization, (c) employment on machine production; (3) increased employment of women. Varying economic conditions in different industries since the War have further disturbed the pre-War wage position, when the rates of skilled and unskilled workers showed no great variation by industry. Such irregularity is a disturbing factor. Existing wages-rates were maintained for a short period after the War by the Wages (Temporary Regulation) Act. Unrest caused the Government to call two national conferences of employers' and workers' organizations which led to extended Trade Board action and further legislation relating to unemployment. Arising from a dispute a royal commission on coal mining was appointed and hours, which under an act of 1908 had been fixed at eight and one winding turn, were reduced to seven, being restored to eight by an act of 1926. In 1919 and 1920 hours in industry generally were reduced to 48 or less, by agreement, without reduction of wages. Depression in industry from 1921 onwards caused considerable unrest owing to reductions in wages, and there was a substantial loss of trade union membership. Recurrent coal-mining disputes led, in 1925, to the appointment of a royal commission, the report of which was accepted by neither side.

A further stoppage in 1926 culminated in a general strike called by the trade union congress general council which, since the War, had steadily increased its authority as the central trade union co-ordinating body. This strike lasted ten days, the essential services being carried on by the Government. There has since been a movement for co-operation between employers and the unions in the solution of industrial difficulties, and few stoppages of work have occurred. Economic difficulties created by the War caused similar disturbances in other countries. While in Great Britain industrial conditions continue still to be settled by voluntary agreements between employers and workers, Governments have taken greater powers of intervention in other countries, e.g., in Russia, Italy, Spain and Germany.

Working conditions may be regulated by employers and workers themselves, by individual or collective bargaining. Whitley or joint industrial councils are a form of standing joint machinery for collective discussion within individual industries. There are also, as part of the voluntary arrangements within industry, conciliation, arbitration or wages boards. The constant problem for the State is the harmonizing of the interests of employers and workers in industry with those of the community, and the conditions under which industry may be carried on have been subject to intervention, in the interests of the workers as citizens, by legislation upon such matters as the establishment of minimum wages, the regulation of hours, insurance against unemployment and sickness, the protection of health and safety and the general welfare of workers while engaged in their work. (*See TRADE BOARDS; HEALTH INSURANCE.*) The adverse effect on the com-

munity of stoppages of work owing to differences between employers and workers has caused States to take action for the avoidance and settlement of disputes.

NATIONAL AGREEMENTS

Collective Bargaining.—Individual bargaining and collective bargaining are terms used to describe the discussion that precedes the making of an agreement concerning working conditions. The former is the discussion between an employer and a single wage-earner and the latter is the discussion between an employer or group of employers and a group of workers with a view to a collective agreement as to working conditions covering all those represented in the discussion. Organization ensures stability to the agreements reached. Unless satisfactory conditions are settled, employers may refuse to give employment or may "lock-out" employees and workers may withhold their services or "strike." Organization gives the workers the bargaining power which is lacking in an individual. It provides also a means of discussion of their desires and for the expert presentation of demands by officials skilled in negotiation and freed from the fear of reprisal which is often present in the minds of employees. Further, the workers in a particular establishment have the support of their fellows in other establishments and a union has resources for obtaining information outside the particular establishment or locality concerned. Collective agreements have effect beyond the membership of organizations both in establishments in which union members are employed and in others. In some cases, however, only union members may be employed, these being called "closed shops" as distinguished from "open shops" in which there is no such restriction. Action to compel non-members to become members often causes serious disputes. The agreed conditions are usually the "recognized" or "standard" conditions in any occupation in a district and under the "Fair Wages Resolution" of the House of Commons, Government contractors must observe these conditions.

There are often national agreements relating to procedure and general matters such as the length of the working hours, relation of piece-rates to time-rates, overtime and night-shift rates of payment, rules for the working of tools, general fluctuations of wages and sliding scales, holidays, apprentice questions, training and employment of workers. Detailed conditions as to wages are sometimes settled nationally but it is more usual for basic conditions to be settled locally, the national organizations confining themselves to the settlement of general changes and to acting as the co-ordinating and appeal authority. Thus the conditions in industries which are carried on in many parts of the country, are adjusted both to local circumstances and to the required degree of uniformity. Wages-rates fixed by national bodies are often graded according to area. The existence of different types of unions with conflicting interests adds to the complexity of collective bargaining. The craft unions, for example, seek to obtain, as far as possible, similar conditions in each industry in which their members are employed. Where there are several unions having members in an industry there are sometimes federations of unions which act as a unit for negotiating purposes.

In some industries, e.g., iron and steel, collective agreements provide for sliding scales of wages based on the selling price of the product or, as in the tinplate industry, on the cost of the raw material, steel bars. In coal-mining, wages vary according to the proceeds of production, after costs have been deducted, determined by accountants appointed by the two sides, the proceeds being divided between wages and management on an agreed basis. The Coal Mines (Minimum Wage) Act 1912 provides for the fixing of district minimum subsistence-wages (by the decision, if necessary, of the independent chairman) by district boards. Other industries have sliding scales by which wages are regulated according to a cost-of-living index figure. The number of these is now greatly reduced and the principle of payment according to the estimated capacity of the industry has been re-adopted.

The enormous number of questions which constantly arise is shown by the complexity and length of collective agreements. The constant association, however, of representative persons of experi-

ence, responsibility and negotiating ability on both sides increases the chance of reaching amicable settlement of the most difficult new problems, and this, together with the adaptability and freedom from rigidity of the system, causes it to be recognized as the main means by which constructive progress towards a merging of the interests of all parties in industry can be made. A new development in this direction is the appointment of joint committees of both sides to examine all the costs and circumstances of an industry with a view to greater efficiency.

Collective bargaining demands for its efficient operation the possession by representatives of adequate authority to bind their members. While some trade union executives have considerable authority, it is usually necessary to take the opinion of the members either by a ballot or through a delegate conference, before agreements are made. It is difficult on some occasions, when discussions have been long and intricate, to convey all the reasons for a particular policy to thousands of workers who have not had the advantage of being present at those discussions. At the same time, the effectiveness of a voluntary agreement depends upon its terms being in general accord with the views of those who are bound by it, and experience has shown that statutory and compulsory measures are practically unenforceable unless this condition is satisfied. In practice the recommendations of leaders carry very great weight.

Collective agreements have a stabilizing effect as, when there is a settled procedure for dealing with questions which may arise, and when the basic conditions are clearly defined and the settlement is for a definite period or subject to termination only after due notice, employers are enabled to enter into contracts with confidence. Where organization is not strong and unions are not able to compel unorganized employers to observe agreed conditions, there is a demand for the statutory extension of agreements, a policy which involves serious practical difficulties.

Collective agreements usually provide for a settled procedure for dealing with disputes in order to obviate stoppages of work. A common form of procedure is for the matter to be discussed first within the establishment. Failing settlement it may then be discussed between the local employers' association and representatives of the union, and then by the national executives, work continuing in the meantime. In the shipbuilding industry in Great Britain provision is made for the appointment of an independent chairman, without the power to give a decision, when there is an irreconcilable difference of opinion on matters other than general wages fluctuations. The fact that a stoppage of work may be the result of failure to settle provides an incentive to agreement. When action is taken in breach of an agreement, the organization whose members are at fault is expected to restore the *status quo ante* pending discussion of the matter in dispute. Stoppages without the sanction of an organization are called "unofficial."

Conciliation, Arbitration and Wages Boards.—Conciliation boards are a form of standing or *ad hoc* joint machinery in organized industries for the purpose of enabling agreement to be reached on matters which ordinary negotiations have failed to settle. They generally consist of an equal number of representatives of employers' associations and of trade unions who are parties to the agreement establishing the board. The rules of some of the boards provide that, in the event of failure to secure agreement, an umpire, arbitrator or conciliator shall be appointed. Some boards limit themselves to wages questions, but conditions settled by general collective agreements are not within the power of boards to alter. The rules of boards usually require that there shall be no stoppage of work pending the consideration of the difference referred to them.

In the iron and steel trade differences not settled in a works are referred to a neutral committee chosen from employers and workers from other works. If this fails there is reference to a board of arbitration consisting of representatives of the two sides with a neutral chairman. In addition there are several standing district wages boards, composed of representatives of the two sides, with, in some cases, a neutral president who may give a binding decision.

In the coal-mining industry there are district conciliation boards composed of equal numbers of both sides. In some districts, if there is no settlement, the matter is referred to an independent chairman. Disputes under the Minimum Wage Act 1912 are referred to statutory joint district minimum wage boards having an independent chairman, who has the power to give a decision.

In the boot and shoe manufacturing industry under the agreement of 1895 there are local boards of conciliation and arbitration. In case of failure to reach agreement an independent chairman is appointed with power to give a decision. There is also a national standing committee of three of each side to deal with all questions arising out of the national agreements. In national negotiations there is a standing independent chairman who acts only as a conciliator.

In the bleaching, dyeing and finishing industry there are standing reference boards, constituted of four representatives of each side to which any dispute on other than a general question must be referred. If the board fails to settle, each side appoints an arbitrator who appoint an umpire. The decisions of the tribunal are final.

The railway services have a form of wages board on which the users of railways are represented. In default of agreement by negotiation, questions are referred to a central wages board constituted of eight representatives of each side. Appeal may be made to a national wages board which is constituted of six representatives of the companies, two representatives from each union and four representatives of users of railways (nominated by the trade union congress, co-operative union, federation of British industries and associated British chambers of commerce, respectively) and an independent chairman. The board must report within 28 days from the date of reference of a matter to it, and it is agreed that there shall be no stoppage of work within that period. This agreement, which is terminable by 12 months' notice on either side, received statutory effect in Part IV. of the Railways Act 1921, but there are no penalties for its non-observance.

The electricity supply, tramways and wool textile joint industrial councils, not desiring arbitration, have adopted interesting *ad hoc* procedure of a combined court of inquiry and conciliation board character, and have referred important matters to boards consisting, in the first two cases, of representatives of the parties, employers' and workers' representatives from other industries and an independent chairman for investigation and recommendations. In the third case the parties themselves were not represented on the tribunal. The councils were free to accept or reject the recommendations but, in fact, they were accepted.

This procedure associated the parties in friendly circumstances in a thorough investigation of facts. Trade boards and agricultural wages committees in Great Britain, wages boards in Victoria and Tasmania, labour disputes committees in New Zealand and the minimum wage boards for home workers in Germany, France, Austria, Czechoslovakia and Norway are of a compulsory character, but they have the characteristic feature of being constituted mainly of representatives of the industries concerned.

Whitley or Joint Industrial Councils.—These are standing bodies which meet regularly for the purpose of discussing not only matters upon which there are differences but also all questions affecting their industry. A committee of employers' and workers' representatives, with the Right Hon. J. H. Whitley, M.P., as chairman, was appointed in 1916 to consider the means of securing a permanent improvement in industrial relations, and to recommend means for securing that those relations should be systematically reviewed by those concerned. The committee stated their opinion that an essential condition of securing a permanent improvement in the relations between employers and employed is that there should be adequate organization on the part of both, that a permanent improvement must be founded upon something other than a cash basis, and that workpeople should have a greater opportunity of participating in the discussion about, and adjusting of, those parts of industry by which they were most affected. They proposed, therefore, a tripartite organization of standing joint bodies, a national joint council for the whole industry, district joint councils to provide the means of discussion in the districts,

and works committees. The constitution of district councils and works committees was to be defined by the national councils, and, throughout, the membership was to be determined by organizations. In the circumstances created by the War, in which centralization of the settlement of conditions became the rule, and the preoccupation of the leaders of organizations with national matters caused them to become somewhat detached from the rank and file in the shops, a shop stewards' movement commenced which threatened to disintegrate the whole system of collective bargaining. The committee's plan was intended to maintain a constant and live connection between the individual members in the individual establishments, and the machinery by which their conditions were settled, and to provide means by which both the interests of individuals and those of the whole industry would receive full consideration. This report gave a new impetus to the creation of constitutional machinery, and, assisted by the Ministry of Labour, joint industrial councils were established in many important industries and services including municipal and Government services. In addition, in industries in which organization was not sufficiently strong for the requirements of a Whitley council, interim industrial reconstruction committees were established. On the railways, station, depot and sectional councils were established to deal with the local application of national agreements, suggestions as to operating and working, and co-operation in obtaining increased business and efficiency. These received statutory recognition in the Railways Act 1921.

The councils are constituted of employers' and workers' representatives alone, except in the case of the pottery council on which there are three independent members in an advisory capacity. The number on each side is not always equal but each side votes as an entity. Usually, unless there is agreement, no action is taken on the proposal under consideration.

The chairman is appointed from among the members and is often, alternately, an employers' and workers' representative or there may be joint chairmen acting in turn. Each council has a written constitution and practically all councils have appointed executive or general purposes committees, the number of council members often being large. Special committees may be appointed such as, in the case of the pottery council, which was the first to be established, the research, inventions and designs committee, wages and conditions committee, organization committee, statistical and enquiries committee, apprenticeship committee. An important rule is that meetings shall be held regularly, usually not less than once a quarter.

Another important advantage of the Whitley council procedure is that all the organizations in an industry meet on one body and there is provided an opportunity of reconciling conflicting interests, and of emphasizing the community of interest of all concerned. There is no settled practice as regards supervisory workers who are generally not represented. In the electricity supply industry, however, there is a separate joint body for the technical and supervisory staff. The national maritime board has panels for (1) masters, (2) navigating officers, (3) engineers, (4) sailors and firemen, (5) catering department. These sit separately to negotiate conditions, the board meeting as a whole when general questions arise. There are district panels which may be divided into sections. Craft unions receive *ad hoc* representation when questions affecting their members are under discussion.

In consequence of the difficult economic conditions since the establishment of Whitley councils, the main subject of consideration, contrary to the intentions of the Whitley committee, has been wages and working conditions, and this subject has been responsible for their breakdown in many cases before they had been in existence long enough to stand the strain. A contributory cause has been insufficient organization on both sides for the effective operation of council decisions. Further, councils sometimes attempted too much regulation by national decisions without adequate regard to local circumstances. Of the councils which survive (about 50) many have found it necessary to delegate considerable freedom to district councils and to confine their action to co-ordination and to the settlement of differences.

Important work has been done by certain councils in research and in the collection of information and statistics. Other important matters considered have been unemployment, education, training and apprenticeship, safety, health, welfare and commercial problems. The docks joint council has carried out important work for the decasualization of dock labour.

It is usual to require differences to be considered by councils before a stoppage of work occurs. Certain councils, *e.g.*, pottery, boot and shoe, printing, do not exercise the function of wage settlement, this being left to agreements between the various organizations, but they act as the conciliating authority in the case of differences involving the possibility of a stoppage of work.

In other countries, there is no general application of the Whitley scheme except in Belgium where organization has grown since the War, and where there are national joint commissions with district and shop councils in many industries.

POSITION OF SHOP STEWARDS

Works Committees and Councils in Great Britain.—

Works committees may be of two main kinds (a) committees of workpeople or their representatives or (b) joint committees of the management and the workpeople. As the works became organized in trade unions, official shop representatives, known as shop stewards or delegates, were appointed either by the workpeople or by the union for various purposes, such as the collection of dues, and representing the workers in the discussion of grievances with the management. During the War the application of dilution and the introduction of payment by results raised many questions of detail, and works machinery gained a new importance. Committees of shop stewards became common and, although in some cases shop stewards of unions of skilled and unskilled workers were in conflict on matters such as the manning of machines, committees were usually representative of all trades in the establishments. The stress of the War conditions in the shops also made it necessary to promote the physical welfare of workers and many welfare committees were formed which were known as works committees. Further impetus was given to the formation of joint works committees by the report of the Whitley committee on works committees. The committee regarded "the establishment of works committees representative of the management and the workpeople, and appointed from within the works, as an essential part of the scheme of organization suggested to secure improved relations between employers and employed," and stated that "in every industry there are certain questions, such as rates of wages and hours of work, which should be settled by district or national agreement and with any matter so settled no works committee should be allowed to interfere; but there are also many questions closely affecting daily life and comfort in, and the success of, the business, and affecting in no small degree efficiency of working, which are peculiar to the individual workshop or factory." They urged strongly that such committees should be set up with the co-operation of employers' organizations and trade unions. There had arisen early in the War a strong shop stewards' movement by association between works organizations in different undertakings which was of a somewhat extreme political character, and which acted independently of trade unions. In Germany, Italy and Russia, and other countries also, such movements occurred with revolutionary results. Trade unions are suspicious of works committees with which they are not directly concerned, in view of the menace to their organization which arises from isolated arrangements. On the other hand, workpeople are apt to lose interest in works committees when the conditions of employment in which they are mainly interested, wages and hours, are settled by other machinery or are otherwise generally satisfactory.

In addition to the creation of works committees following the Whitley reports, the position of shop stewards was regularized in some industries, *e.g.*, engineering, in order to enable works discussions to be conducted in a constitutional manner and with due regard to existing agreements in the industry.

Works committees are sometimes composed entirely of individual workers elected by ballot, secret or otherwise, by occupa-

tions or by departments. Some are composed entirely of members of trade unions so elected. In some cases officials of unions may attend meetings regularly or in special circumstances. In large undertakings there is often a general committee comprised of delegates from departmental committees. It is usual for meetings to be allowed during working hours and for wages to be paid for time so lost. Among subjects which are dealt with by works committees are welfare, benevolent, holiday and loan funds, pensions schemes, sports and recreation, accident prevention, share-purchase schemes, piece-price fixing and education. In some cases dismissals of individuals, or, in case of slackness of business, of numbers of individuals, are subject to review by works committees. This is greatly valued as it gives individuals greater security of employment and protection against victimization. At a time of depression prior consultation enables plans for the sharing of work or regularization of employment to be discussed. Methods of production, regularity of output and prevention of waste are other matters dealt with by committees. They are in some cases informed regularly of the state of business.

Works Committees in Other Countries.—The works committee movement was stimulated in other countries, as in Great Britain, by the War circumstances. In Europe, it was influenced also by the revolutionary movements between 1918 and 1920 based on workers' and soldiers' councils. Between 1919 and 1922 Germany, Austria, Czechoslovakia, Norway and Luxembourg passed laws on the subject. In Japan, works councils of varied types have continued to be established in many undertakings, always as purely advisory bodies. Both labour organizations and works committees have established themselves but the interests of the two forms of organization are not yet reconciled. In Russia industrial establishments are generally controlled by workers' committees in association with trade unions, the latter being strongly represented on the governing authorities of the country. In other countries provision has sometimes been made for particular industries such as railways and mining.

In Germany the Weimar Constitution provided for the establishment of workers' councils, regional workers' councils and regional economic councils, a federal workers' council and a federal economic council, all in organic connection. A provisional federal economic council was established, which has now been reconstituted, but regional councils have not been set up. The Works Councils Act of 1920 was not in accord with this workers' control movement which was antagonistic to trade unions. This act provided that "workers' representative bodies" should be established in all industrial and commercial undertakings, including agriculture but excluding shipping, employing not less than 20 persons. Within the council there are sections for wage-earners and for salaried employees. In smaller undertakings employing more than five persons, shop stewards were to be appointed. Appointments, which are for a year and can be terminated only by a labour court, are confined to workers aged 24 years and upwards with not less than three years' continuous service and are made by ballot of workers over 18 years old. In certain circumstances a representative body set up by collective agreement ("tarifliche Betriebsvertretung") may be substituted for a works council. In a composite undertaking a joint works council ("Gesambetriebsrat") may be formed, the councils for the constituent works continuing to function. In exceptional cases a "common works council" ("gemeinsamer Betriebsrat") may be formed, the individual works councils being eliminated. Representatives receive their wages for the time spent in their work in that capacity within working hours. By an act of 1922 one or two members of works councils are appointed to the control board (this is not a board of directors) of a joint stock company, a limited partnership with share capital ("Kommanditgesellschaft auf Aktien"), a registered co-operative society, a mutual insurance association, a company established under the mining laws, or, optionally, the control board of a limited liability company. Agreements between works councils and employers must always be subordinate to any collective agreements in force. Subject to this, the councils deal with such matters as wages and other working conditions, methods of production, staffing, discipline and dismissals, and employers must keep

the councils informed of all action taken which affects these matters, of the trading position of the undertaking, and of the anticipated demand for labour. In large undertakings a profit and loss account and a balance sheet must be presented and explained. In case of disagreement with the employers appeals may be made to the State conciliation boards and the labour courts. These appeals resolve deadlocks and are substantial aids to the maintenance of peace. The power given to the council in respect of the review of dismissals is highly valued.

Since the years of depression 1923-25 the councils have largely disappeared from commercial establishments. In spite of the statutory provisions, the working of the councils has been to a considerable degree dependent upon the extent to which the workers have been organized in trade unions. There is, however, a tendency among some employers to favour works agreements in place of general collective agreements. The trade unions have tended to become industrial unions covering whole industries, and have formed organizations of works councils corresponding with the main groups of the trade union movement, with works councils headquarters in various localities, divided into groups for each branch of industry. There is a trade union central works committee for the whole country and all the councils are linked up in industrial groups. A movement of some importance has been the linking up of the councils in undertakings which form vertical trusts, *i.e.*, covering the whole process of production from the raw material to the finished products. These are voluntary associations known as trust works councils ("Konzernbetriebsrat"). The effect on the trade unions has been to cause them to concentrate more attention on the production problems of industry and to produce a type of leader who is more closely associated with the work and the workmen in the undertakings.

In Austria the act of March 15, 1919, is similar to the German act. Agriculture is excluded and there are special arrangements for railways, Government departments and postal services. Disputes with regard to the working or establishment of councils are referred to a conciliation board which usually works through committees constituted of one representative nominated by the employers and workers, respectively, and an impartial chairman, usually a judge, all appointed by the Ministry of Social Administration. Failing settlement by agreement the board gives a final decision against which there is no appeal, but the administrative court, which is not in terms debarred from action, has allowed appeals to be made to it. In Austria the expenses of the councils other than wages are a charge upon the workers.

EXTENT OF STATE INTERVENTION

Conciliation and Arbitration.—Conciliation and arbitration form an important part of State intervention in every country. In Great Britain conciliation or arbitration action can be taken only with the consent of the parties. In Germany, Denmark, Sweden, Finland, Norway, Austria, Holland, Australia, New Zealand, South Africa (public utilities) and in some South American countries, conciliation procedure can be enforced on the parties. In Belgium, unless conciliation procedure is utilized, the parties are penalized in respect of payments from the unemployment insurance fund. In Australia the presidents of arbitration boards or conciliation committees have power to intervene on their own initiative before the compulsory arbitration procedure, which follows failure to settle, is put into operation. In Italy there are "co-ordinating bodies" which have a statutory right to intervene and stoppages of work are prohibited. In Germany the proposals of conciliation tribunals, if not accepted, can be made binding on the parties, although the use of this power is strictly confined to disputes seriously affecting the public interest. In Austria the conciliator may proceed to arbitration. In Norway a stoppage of work can be prohibited by the conciliator pending conciliation proceedings and a settlement by arbitration may be ordered in disputes endangering the public interests. In Denmark, Sweden, Finland and New Zealand the conciliation authority may make proposals and publish them with the facts. In Italy the "co-ordinating bodies" may determine the conditions to be put into operation. In Holland the facts as elicited by conciliation proceedings may be pub-

lished or, in serious disputes, a committee of investigation may be ordered. In Canada, besides conciliation under similar conditions to those in Great Britain, there is, in respect of five provinces, power to compel submission of a dispute in mining, transport and public utility industries to a board of conciliation and arbitration, stoppage of work in the meantime being prohibited.

There is usually provision for arbitration in which a decision is made on the matters in dispute by a third party, either a single arbitrator, a board of arbitration or a labour court. Arbitration may be voluntary and the awards open to voluntary acceptance, or compulsory in both cases.

The great difficulty in compulsory measures is the enforcement of penalties when large numbers of workers are involved. Moreover, the fact that either party can force the other to arbitration tends to make conciliation procedure ineffective. Conciliation and arbitration machinery is constantly being modified in the various countries. National circumstances and psychology, the size and distribution of the population, the nature of the industries, and the economic conditions prevailing must all be taken into account in estimating the suitability of the machinery in any country.

Great Britain.—Although there had been much legislation relating to the settlement of disputes and the regulation of wages, the only effective action until 1896 was the operation of agreed conciliation arrangements within various industries, based on the inherent desire of those engaged in industry to settle their own affairs, against which compulsory systems have never been more than partially successful in this or any country. Other reasons for the failure of legislation were dislike of appearance before justices of the peace, unwillingness to trust untried arbitrators and the severe penalties for non-observance of decisions. The Conciliation Act 1896 removed all elements of compulsion and gave the Board of Trade power to promote the settlement of disputes by conciliation or arbitration by consent of both parties, and to establish standing conciliation boards. In 1908, standing panels of independent chairmen, employers' and workers' representatives were appointed with a view to assisting parties in making their nominations for arbitration proceedings. Increasing unrest caused the appointment in 1911 of an industrial council of 13 representatives of employers and workers respectively, with Sir George (now Lord) Asquith as chairman. The council proved to be too large to be effective for either conciliation or arbitration and ceased to function. In 1912, for the settlement of a coal-mining dispute, the Coal Mines (Minimum Wages) Act, which provided for the fixing of minimum conditions by 22 district joint committees with independent chairmen, was passed. During the War it was of vital importance to prevent stoppage of production and, under the Munitions of War Acts, compulsory arbitration, with the prohibition of strikes and lock-outs, came into operation. The effect was that the slower procedure of negotiation or conciliation was largely abandoned. As so much work was for Government purposes and increased wages were reimbursed by the consumer, employers had not the same financial interest as under normal conditions. Even in War circumstances, however, the legal prohibition of strikes was only a qualified success and, as in Australia, was ineffective when large numbers were concerned. The Whitley committee made a recommendation against compulsory arbitration but in favour of a standing arbitration tribunal as a part of the voluntary machinery, and the Industrial Courts Act 1919, which superseded the Conciliation Act, complied with these recommendations. Part I. provided for a standing industrial court consisting of a president and panels of representatives of employers and workers, including women members, and independent persons, the expenses being borne by the Government. A court is constituted by the president and usually consists of three persons. There is power also to utilize technical assessors. Cases are referred to the court, by consent of the parties, by the Ministry of Labour, the terms of reference, as in all arbitration cases, being agreed upon by the parties. Terms of reference define the issues upon which a decision is required. Requests for interpretations of the court's awards may be referred direct to the court by either of the parties. The awards are not of compulsory application. For civil service cases, which, under an agreement,

are referred to the industrial court for settlement, there are special panels nominated by the chancellor of the Exchequer and the staff organizations, respectively. Part I. of the act also provides that any trade dispute may be reported to the Minister by either party to a dispute and the Minister may take expedient steps to promote a settlement. If both parties consent, he may refer the dispute to the industrial court or to one or more persons appointed by him or to a board of arbitration of one or more persons nominated by each side, and an independent chairman appointed by him. Boards are sometimes constituted of an independent person, by whom the decision is given, with assessors, the object of the latter being to provide the former with the assistance of experienced persons from either side for the elucidation of facts, and to give the parties the assurance that the points in their case are made clear when the award is made. The policy is based on the acceptance of the principle of the general regulation of industrial conditions by collective agreements and, to minimize Government intervention, the act precludes the Minister from referring a dispute to arbitration unless existing agreed arrangements in the trade for the settlement of disputes have been exhausted.

Although arbitration awards are not compulsorily binding, agreement to refer a dispute to arbitration is regarded as a settlement of a dispute, work being resumed in the case of a stoppage on the conditions operating when the stoppage occurred. Arbitration proceedings under voluntary conditions are informal and are free from restrictions such as apply to proceedings in courts of justice. The parties are encouraged to state their case freely and without hostility.

For the purposes of its conciliation work the Ministry of Labour has six district conciliation officers who keep in touch with industrial movements in their areas. Discussion with an impartial and experienced person at an early stage often directs negotiations into a course which leads to an amicable settlement. Circumstances arise in which one party cannot approach another or make proposals for settlement without the appearance of giving way, and in such cases a mediator renders useful service. There is no general prohibition of strikes and lock-outs but strikes in breach of contract are illegal, under penalty, in gas, water, electricity supply and local authorities' services (Conspiracy and Protection of Property Act 1875, Electricity Act 1919, Trade Union Act 1927).

British Colonies.—In Australia there is a Commonwealth court of conciliation and arbitration, with a justice of the High Court as president, which deals with disputes extending beyond the boundaries of any one State, and each State has a wage-fixing authority which also deals with industrial disputes. In New South Wales there is a court of arbitration with district courts and an appeal court of three judges. Subject to the court of arbitration's control, industrial boards for any industry or section of industry, or combination of industries may be established to deal with matters referred to them by the court. There are also conciliation committees and officers with power to call conferences. Stoppages of work are illegal in public utilities, in industries covered by awards or agreements (unless, by secret ballot of two-thirds of the members, an award is no longer binding, and when 14 days' notice of strike has been given). The Government can order a secret ballot. A minimum living wage is settled by the State Board of Trade. In Queensland there is a court of arbitration of not more than three judges, which may regulate conditions, with or without application, remit disputes to industrial boards, hold inquiries and fix a minimum living wage. Strikes and lock-outs by organized workers and employees are prohibited unless authorized by secret ballot or, in others, unless authorized by the court after a secret ballot. In South Australia there are an industrial court and industrial boards with an appeal from the latter to the former. Strikes and lock-outs are prohibited and a minimum wage is settled by a board of industry. In Western Australia there is a court of arbitration and strikes and lock-outs are prohibited. Awards and agreements filed with the courts are binding throughout industries or districts in all cases. In Victoria and Tasmania there are wages boards in each industry which fix

minimum conditions, the determination being referable in Victoria to a court of industrial appeals for confirmation or revision. The Federal court, unlike the State courts, has not power to determine industrial conditions otherwise than in the settlement of a dispute, but State courts cannot fix conditions inconsistent with those fixed by the Federal court. The Federal court fixes a basic living wage independently of those fixed by the States. The president of the Federal court can call compulsory conciliation conferences and the court may refer disputes to a conciliation committee or local board. Under the Industrial Peace Act 1920, a Commonwealth council of employers' and workers' representatives with an independent chairman was appointed to inquire into disputes and provision was made for special tribunals and local boards with power to make compulsory awards which may modify those of the court. The legislation generally is operative in the towns and difficulty arises owing to overlapping of Federal and State decisions.

In New Zealand the system of compulsory arbitration applies to registered unions. Disputes are referred to the court of arbitration if they have not been settled by a district conciliation officer sitting with assessors as conciliation councils. These have compulsory powers. A strike or lock-out is prohibited while a dispute is under consideration or during the currency of an award. For other workers there is compulsory reference of disputes to a conciliation commissioner and later to a labour dispute committee composed of representatives of the parties and an independent chairman. Failing a settlement within 14 days of the publication of a committee's findings, a secret ballot may be taken. Strikes and lock-outs are prohibited if an award or agreement is in force or a period of three weeks has not been allowed for investigation and a ballot. The provision as to awards and agreements is similar to that in Australia. A minimum wage is in operation.

In South Africa strikes in public utility undertakings are prohibited and compulsory arbitration applies to these cases. The main provision for the settlement of disputes is by the creation of joint industrial councils in organized trades and boards of conciliation in others. The Minister of Labour can appoint arbitrators on application and if a majority of employers and workers agree to be bound by the award a stoppage becomes unlawful before the award is issued. Agreements may be made binding in any district.

Other Countries.—In Germany there are Federal and district conciliators and district conciliation committees. Failing success, an "adjustment board" consisting of a conciliator with assessors may be appointed. Failing agreement, an award may be made which may be declared binding. This, however, is put into operation only when the dispute menaces the well-being of the community as a whole. Either party can apply to have a decision made binding, and the party that refuses to accept it is legally liable for loss, damage or other consequences. Unless there is adequate evidence to the Minister of Labour that it is financially impossible to carry out a compulsory award, an establishment may be compelled to carry on under Government supervision. An act of 1926 provided for the establishment in 1927 of local, State and Federal labour courts with jurisdiction, to the exclusion of civil courts, in civil disputes affecting collective agreements, or arising out of employment or apprenticeship, or concerning a contract of employment, or arising out of the Works Council Act but not disputes on claims for new conditions of employment. The local and State courts are divided into chambers for manual and non-manual workers, and special chambers for crafts or disputes in particular occupations, constituted of a judge and assessors. The Federal labour court is a branch of the Federal court of justice.

In Italy, under the act of April 1926, strikes and lock-outs are prohibited. Provision is made for the recognition of one association only for employers and workers, respectively, for each occupation in a district, the associations being federated. There are six employers' confederations covering large sections such as industry, agriculture, commerce and one confederation for trade unions, which have authority over the constituent associations, approve collective agreements and give permission for action to

be taken before the labour magistracy. There are also national federations under the confederations. Agreements between associations are binding under penalty on all employers and workers in the category and district covered. All organizations are controlled by the Minister of Corporations. Co-ordinating bodies or corporations of employers' and workers' associations may deal with collective labour questions and disputes. For the purpose of settling disputes arising out of collective agreements or demands for new conditions of employment there is a labour magistracy constituted, as special sections of the 16 courts of appeal, of the president and two experts on production and labour, with an appeal to the court of cassation. A charter of labour defines the position of the Fascist State in relation to problems of labour and production.

In Norway, following serious disputes in 1927, compulsory arbitration was re-introduced by the Labour Disputes Act. If conciliation (which may be compulsory) fails to settle a dispute and it is likely to injure public interests the Government, on the report of the national conciliator, may order settlement by arbitration and prohibit a stoppage of work. Ballots on proposals made by conciliators may also be required and a report made giving the numbers voting for and against the proposal. In any case stoppage of work must not commence within four days of notice being given to a conciliator.

In France there are, as in Belgium, conseils de prud'hommes which conciliate in disputes affecting individuals. These consist of a justice and representatives of employers and workers. There is also conciliation by Government officials by consent of the parties.

In Belgium there is a system of conciliation boards, constituted by industries themselves or by the Government. Employment exchange committees also have power to intervene in disputes.

In Austria there are central and district conciliation boards, the chairman acting alone in the first place. The boards may act as arbitration tribunals. Factory inspectors also act as conciliators.

Enquiry and Investigation.—In various countries special action is taken by Governments with a view to informing the public of the facts concerning disputes. In Great Britain under Part II. of the Industrial Courts Act, the Minister of Labour may appoint a court of enquiry to enquire into matters connected with an existing or apprehended dispute. Sixteen courts have been appointed, two of which were in respect of coal mining and three in respect of docks. The appointment of courts is entirely within the discretion of the minister and does not depend upon the application or consent of parties to a dispute. Courts have been constituted of an independent chairman and representatives of employers and workers, usually one of each chosen from industries outside those involved in the dispute. All are nominated by the Minister. A court may require any person to give evidence before it but no penalties are attached for refusal to do so. Evidence may be required on oath but this power has not been used.

The above provisions were based on the Industrial Disputes Investigation Act 1907, of Canada, which, however, is of a more compulsory character, and is confined to mines and public utilities. During the War its scope was extended temporarily and boards may be appointed in other industries by joint consent of parties. A board of conciliation and investigation may be appointed by the Minister of Labour on his own initiative or on the application of a party to a dispute. In practice boards have never been appointed except on such application which must be accompanied by a declaration that a stoppage is imminent. When a board has been applied for or appointed, a strike or lock-out is prohibited under penalty pending the report of the board. Thirty days' notice of changes in working conditions is required. A board consists of one member nominated by each party and an independent chairman agreed upon by the members or nominated by the Minister, the latter being the usual procedure. There are penalties for failure to attend or supply evidence but these do not appear to be enforced. Of the 642 cases up to 1926 in which action was taken either by conciliation or by the appointment of a board, a stoppage was averted or ended in all but 37 cases. In all these cases one or both parties had indicated by making application, a desire to avoid a stoppage. Where illegal stoppages have taken place no

action has been taken by the Government, enforcement being left to the parties. In the report of the Nova Scotia coal commission in 1926 it was indicated that the commission had come to the conclusion that the power of a party to secure the appointment of a board of investigation, if and when it so desired, had the effect in some cases of making prior negotiations unreal and of operating against the settlement of disputes by the parties themselves. It has also been suggested that the existence of this power has caused claims to be made and to be pressed to the point of a dispute which would not otherwise have been allowed to reach that stage. The administration of the act, like that of the Industrial Courts Act, has been on a voluntary basis.

In 1925 the act was declared by the judicial committee of the privy council *ultra vires* of the Dominion parliament under the constitution. The act has since been amended to render it possible for each province to make itself subject to the provisions. British Columbia, Saskatchewan, Manitoba, New Brunswick and Nova Scotia have passed laws for this purpose.

In the Netherlands there is similar power to appoint a committee of enquiry in a dispute which may seriously affect the interests of the community and in which at least 300 workpeople are involved, if all other means of settlement have failed.

Under the Australian Industrial Peace Act, the Commonwealth council of employers and employees may appoint committees of enquiry and may itself conduct enquiries, and in many countries conciliation officers and conciliation tribunals have power to publish facts and recommendations. In New Zealand this action is taken for the purpose of allowing the proposals to be balloted upon.

In special circumstances, royal commissions are appointed in Great Britain. These are established by act of parliament and have power to compel persons to attend and to supply evidence. This procedure permits a longer and more thorough investigation than is possible to a court of enquiry which has to act in the difficult circumstances created by a threatened or existing stoppage of work.

THE UNITED STATES

Industrial Relations in the United States have been coloured at every turn by the individualistic traditions of the country and by the absence of caste distinctions. These two strains in American life should be kept in mind in attempting to understand the various aspects of labour relations, such as trade unionism, social

legislation, arbitration and conciliation, and the latter-day emphasis on securing co-operation within the individual plant. The relations between employers and employees can be divided into a controversial phase and a constructive phase, though these aspects overlap. The historical developments are largely concerned with the controversial phase.

Trade Unionism.—American trade unionism has quite a different complexion from the European. In Europe unionism has fulfilled not only economic functions but also political and social; its purpose has been not only to raise the economic status of the worker, but also to compensate him for his inferior social status by giving him vicarious prestige through the power of the unions. In America, on the other hand, labour organization has largely taken the form of "business unionism" for purely practical bargaining purposes. Unionism in the United States is a much more recent phenomenon than in other countries. The industrial revolution, which was in full swing in England around 1800, did not produce its full effects in the United States until about the middle of the century. Thus American unionism did not gain any momentum until after 1850, and no existing union traces its history beyond that time. In colonial days, the newness of the environment, the predominance of agriculture, the local industrial development retarded through the fixed policy of the English Government, kept difficulties between organized workers and employers from being a national problem. The earliest known workers' association is that of the Philadelphia shoemakers of 1792, which was followed by a few other sporadic societies. It was not until the end of the first third of the century that labour organizations became numerous enough to be conspicuous.

Even to-day union organization has not reached foreign proportions. As late as 1900 the American Federation of Labour (q.v.) embraced less than 600,000 members. At present the total membership of all unions combined is less than 4,500,000. The late development of trade unionism is perhaps one reason for this; another is the persistent opposition of employers. Various court decisions have made organization more difficult, since unions do not have the legal position they achieved in England. In some of the recent decisions of the supreme court it has been made illegal for a union to attempt to organize workers into unions if these workers have signed a so-called individual ("yellow dog") contract with the employer agreeing not to do so. Union leaders have also complained that the process of injunction has seriously hampered their activities.

Unionism is embodied largely in the American Federation of Labour, a loosely federated group of national unions, each to some degree with its own economic aims. But there are certain characteristics common to all groups. American labour for the most part has for over 40 years renounced the struggle for independent political power and is the most determined enemy of communism and, to a large degree, of socialism. There has been much bitterness against individual and group employers, but the philosophy of class conflict as such is not much in evidence. American workers are not inclined to regard their status as immutable. It is true that unions, though started with economic purposes, soon took on a considerable political complexion. But though at first they attempted to use legislation to improve the conditions of the worker, latterly they have shown little interest in labour legislation and indeed at times union leaders have opposed certain measures intended particularly for the benefit of the worker.

Equality of citizenship for the wage earner was a much nearer goal for early American unions than it was for those in other countries. A political democracy had already been established in principle. A few States still lagged behind with property qualifications attached to the franchise, and these and other injustices gave occasion for a good deal of political activity. But with the advent of practically universal suffrage it was easy to remedy certain other abuses. The unions took a prominent place everywhere in intensive campaigns to abolish imprisonment for debt, to establish laws providing for a mechanics' lien, to reform the regulations concerning compulsory militia service, to develop a system of public education having no taint of charity, and to exclude Mongolians from immigrating to compete with American

workmen.

With success in the more purely political programmes, unions turned to legislation for economic reforms. The limitation of hours of labour formed the earliest of the major issues upon which labour organizations co-operated. They were successful, in 1840, in securing, by an executive order of President Van Buren, a limitation to ten hours a day for certain Government employees, and in 1868 in securing, through the action of Congress, a general eight hour day for these employees.

When, however, labour unions tried to secure the limitation of hours and the improvement of wages and other economic conditions in private industry through Government action, they encountered such obstacles that in time their faith in this approach was much weakened. Among the difficulties which they met was the hostile attitude of the agrarians on the one hand, who were not much in sympathy with legislation pampering the city workers, and of the employers and the commercial group on the other. Furthermore, progress had to be achieved in 48 States. Not only had public opinion to be roused, but legislation had to run the gauntlet of the courts and be watched at every point to keep it from being nullified by ineffective enforcement. The courts proved the greatest obstacle, for they were none too favourable to legislation suggesting an abandonment of freedom of contract. Latterly, therefore, unions have evinced comparatively little interest in labour legislation and have to a large extent left the field to outside groups. (See further TRADE UNIONS.)

STATE AND WORKER

Labour Legislation.—In recent years, labour legislation has been largely promoted by public groups composed neither exclusively of employers or of unions. Progress, however, has been hampered by the individualist traditions of the country. Then again, though there were many examples of unsatisfactory conditions in factories, it is probable that they existed to no such extent as they did in the early English factories, or in Continental factories. The result was no such intense reaction as in England to bring about a public outcry for labour legislation. Besides, labour legislation had to meet the usual criticism that it was based upon "foreign socialistic ideas." There was little sympathy with German bureaucratic ideas and as such legislation found its most scientific exposition in Germany, the cry that it was un-American and collectivist was easily raised against it.

As a result, there is no health insurance law, old-age pension provisions or unemployment insurance law in any State in the Union or in the Federal Government. Many of the larger companies have made elaborate provision for pensions, health insurance and even group life insurance, but of course this has left the employees of smaller companies without protection of this character. The various attempts to regulate child labour federally have been upset and the constitutional amendment was defeated by an overwhelming vote of the people, so that this regulation of child labour must depend upon the various types of legislation passed in each State in accordance with its own particular standards. Minimum wage legislation for women and children which has been on the statute books in 14 of the States, was recently interpreted so unfavourably by the United States Supreme Court as largely to nullify it.

But in factory codes, sanitary regulation and safety provisions State regulation has decidedly advanced. This has been accompanied by a wide-spread safety movement on the part of employers, resulting in part from the recently awakened interest in systematic management, and in part from an admirable system of workmen's compensation in approximately 40 States. This legislation, once bitterly opposed by the employers, now includes industrialists as its strongest supporters.

Mediation and Arbitration.—In accordance with the conflict theory of labour relations, a technique of mediation and conciliation was developed both in the Federal and State administrations, and within industries in private contract between groups of employers and the unions. But compulsory arbitration of the type developed in Australia has made no headway. For the most part Governmental intervention has avoided compulsion and relied

upon the friendly offices of governmental agencies in investigating the dispute and bringing the parties together. The only element of compulsion is the power to summon witnesses, hold hearings and command evidence. The distinction has been made that there is more cause for the State exercising compulsion on essential industries than on so called non-essential ones. Nevertheless, neither in Federal or State legislation has compulsion obtained any permanent foothold. In only two important instances—the Colorado law of 1915 and the Kansas “Court of Industrial Relations” of 1920—has an element of compulsion been included. In the latter instance, the law met with determined opposition on all sides and was declared unconstitutional by the United States Supreme Court so far as it applied compulsory arbitration to other than transport or public utilities, and was superseded by a new law which abolished the court.

Federal legislation applicable to disputes on transportation corporations engaged in interstate commerce began with the act of 1888, and gave the president power of voluntary arbitration, and of making an inquiry into the facts that would make it easier to settle such disputes. The principle of voluntary arbitration was maintained in the Erdman Act of 1898 and the Newlands Act of 1913, the successive laws which superseded the act of 1888. The Transportation Act of 1920 gave certain powers to render awards to the National railway board. Though the awards of that board were not legally binding there was dissatisfaction with the element of compulsion which inhered in its powers to invoke public opinion without the submission of both parties. Largely as a consequence of this dissatisfaction the latest law, the Railway Labor Act of 1926, abolished the provision for such a board. Voluntary mediation and arbitration are outstanding features.

The prejudice against compulsory arbitration has had a definite basis in the fear that under a system of compulsory arbitration awards would finally be made even in matters of minute detail.

Thus both nationally and locally judicial process has been confined to conciliation and voluntary arbitration. A department of conciliation was included in the scope of powers of the Federal Department of Labor by an Act passed in 1913, and its commissioners intercede whenever a situation suggests that they may be able to prevent a break. National commissions have also been appointed to take testimony on important strikes and to recommend the principles upon which the issue should be settled and these have also been of a voluntary character. One of the outstanding ones was President Roosevelt's anthracite coal commission of 1902, whose report was long a basis of agreement.

Within the field of private agreement there have been many experiments in setting up judicial machinery, such as the protocols of the New York garment trades, in which a complicated extra-legal industrial Government was established. Since the background for such experiments have been grievances, the subject was handled largely from a juridical point of view, rather than from the point of view of co-operation and production, as is the case in the more recent clothing agreements.

These processes of mediation and conciliation, and judicial processes as a means of solving the labour problem, have been given a disproportionate popular interest. For a while there were indications that they were regarded by many as panaceas, but recently the attitude has changed.

CONSTRUCTIVE PHASE OF INDUSTRIAL RELATIONS

Since about 1910 a movement has developed to introduce into management scientific and professional principles. One of the first points was the importance of a highly co-operative employee morale. It is true that many aspects of personnel management may have been introduced as a defence against unionism and to this extent may be involved in the controversial phase of industrial relations; but its main impulse has been constructive. This new conception of labour relations as part of management has introduced a constructive attitude towards the labour problem and prevented it being regarded inherently as a matter purely of unionism, legalism, conciliation and arbitration or legislation. The way has thus been made clear for the adoption of a broader perspective, in which the items mentioned above are

given a place, but in which other aspects, previously neglected, are accorded their due prominence. These aspects are those dealing with the proper organization of work relations in each plant.

Differences in morale and in satisfaction with their daily job between the employees in two organizations may have no relation to the wages paid. There are examples of factories existing side by side in the same vicinity paying the same wages in one of which there is a contented working force and in the other a dissatisfied, restless group. Sometimes, where there is a disparity in wages, the concern paying the higher wage has the dissatisfied workers. The difference is one in technique,—the degree to which *system* and practical common sense have been applied to the every-day problems of living and working together.

Present day interpretation of the labour problem adds to the old-time conception of “the economic man,” invented by the economists, and described as one struggling for his share of what is provided, the conception of “the administrative man,” who has his place in industry as a unit in a complicated organization. In other words, we now recognize that in any private business plant there is, in addition to the economic side of industrial relations, a purely administrative problem of organization and functions. This problem in an industrial concern is not very different from that which arises in a Red Cross or consumers' co-operative organization, in the post office, and in other agencies which also are trying to provide services, and in which no question of capital or labour is involved. There are laws of sound administration as well as “economic laws.”

Realistic analysis has, furthermore, taken out some of the misplaced conflict allocated to the factory. It has been recognized that the determination of real wages takes place chiefly not within but without the factory walls in the competition between industries and in taxation, and that often the contest for the economic surplus is not solely, or even for the most part, between capital and labour but between various other groups. Agricultural workers are pitched against industrial workers, employers and employees in one industry against those in another. Sometimes the inequalities between groups are due to the vagaries of credit and monetary systems. Though the economic struggle has been dramatized as taking place in the factory, only a very small part of that struggle in fact takes place there.

Thus, the modern United States emphasis in the treatment of the difficulties of industrial relations is upon the improvement of the more routine problems in the individual factory.

Attention to the administrative aspects has developed a “technique of good will,” with an extensive literature going under the general title of personnel administration. The problem has been to satisfy the desires of workmen within the limits of the requirements of productive efficiency and to see how productive efficiency could be furthered by this satisfaction of workmen's aspirations.

Modern behaviouristic psychology has been invoked to satisfy these desires. They may perhaps be roughly classified as the desire for justice, the desire for status and the desire for opportunity. The first, “justice,” is the elemental desire for fair play; “status” is the desire of the workman for some recognition of his dignity as a participant in the industrial activities, and “opportunity” is the desire of a certain proportion of the employees to forge ahead. As a step in the effort to satisfy the desire for justice might be included the pension systems and provision for health and group life insurance which have been set up particularly by the larger companies. At times these are established on a basis under which the employees contribute to the fund and at times on a non-contributory basis. To satisfy the desire for status the technique that has been developed has been that of works councils and employee representation, employee stock ownership and similar plans.

Employee representation is probably one of the most interesting aspects of the new personnel movement. Feeling the need of providing some form of group expression to the workers, executives have introduced employee representation having no connection with trade unionism as such but in a way as a substitute for unionism. Over 1,500,000 individuals are employed in concerns operating such plans.

In some plans the function of the employees' representatives is purely advisory. No vote may be taken and the advice is not necessarily followed, but the employees realize that at least their viewpoint has not been entirely ignored. On the other hand, there are types in which preliminary legislative power is given to employees' committees on matters of employee interest; this may be subject to the veto of the management or may provide for outside arbitration of issues.

The method of satisfying the desire of the workman for "opportunity" is to recognize that what the more energetic workman particularly desires is a successful career. In order to satisfy this desire, elaborate systems for detecting, training and promoting workers have been established in many plants. Much effort has been made to evolve systems of training and methods of making promotion available to able employees. These are particularly necessary in America because of the decline of the apprentice system. It has been estimated that only a minority of employees are really ambitious for advancement, but it is recognized that it is important to train and advance this group, however large it may happen to be.

In connection with this desire of the workman for opportunity can be included the large question of security of employment, as an essential aspect of making the worker's job a career. The individual employer cannot do much to prevent the effects of cyclical unemployment, but he can temper its effect. Much attention has been given to seasonal unemployment, particularly by some large corporations. Here the subject of industrial relations becomes involved in the larger problems of management, for to do away with seasonal unemployment the production manager must plan skilfully and the financial and sales executives of the company must co-operate in stabilizing operations.

In the dispensation of justice and in the more general problem of carrying out a personnel programme it has been recognized that specialized machinery is necessary. As a result progressive companies have established "employment" or "personnel" departments. This is particularly important because new groups of employees are constantly being marshalled into new industries. Formerly the theory in certain plants was that any worker could see the general manager or the employer. Now it is recognized that it is impossible for the able manager to give time to these matters, and that injustice was often done to the workman because of inadequate provision for the specialization of this function. Hence the necessity of such departments has been accepted as particularly important in large companies.

Among other things the purpose of such a personnel department is to make certain that the employees are treated fairly and grievances adjusted at the source. Complaints are handled in such departments with a works council acting mainly as a court of appeal. In some cases the right of "firing," as well as the right of hiring, has been taken away from the foreman, and though there were misgivings at first, this system has worked fairly successfully. The trend is not to have these matters settled in a juridical fashion but as matters of adjustment.

Personnel administration and the larger movement for thorough and systematic management have become fused, and tend towards the fading of class distinctions, the existence of which has been known to interfere considerably with efficient organization.

This new attitude of employers to their labour problems as a part of good management has served as a challenge to trade unionism. This has been particularly true of the employee representation movement where there have been some interesting attempts on the part of the union to join with management in "union-management co-operation." The most notable example is on the Baltimore and Ohio railroad in which the shop crafts and the railroad company have been working out methods of furthering their mutual responsibility for successful production. Another example of unionism in a constructive relation may be found in the men's clothing industry. In this industry the trade union has assumed a very real responsibility for securing production, and an elaborate plan of unemployment insurance and production standards has been worked out. There have been other examples of what may be called industry-wide co-operation

between unions and employers. It must be confessed, however, that the greatest progress in industrial relations has been made in the better adjustment that has been worked out as a part of good management in the individual plant in abolishing any difference in the treatment of the rank and file of workers and other members of the organization.

ARBITRATION IN THE UNITED STATES

In general, any business controversy may be submitted to arbitration. Experience has proved, however, that arbitration is more particularly adapted to the following general categories of controversies: differences concerning the interpretation of the terms of a commercial contract; questions involving the interpretation of commercial custom and the application of trade rules in determining such questions; matters involving professional skill or opinion as, for instance, in architectural and engineering undertakings; trade disputes where questions concerning quantity, price, quality or other question of classification arises; controversies arising out of contracts relating to public undertakings; matters of dispute between partners; disputes under leases or transactions in real property except, perhaps, where some questions of title are involved. The United States Arbitration Act also facilitates arbitration in the general field of maritime transactions and in foreign and interstate commerce.

Systems of commercial arbitration may be classified into two general types: (1) where, in the absence of or without regard to any statutory provision, the parties submit the matter in controversy to the decision of other persons and where performance of the terms of the agreement must depend solely upon the good faith of the parties; (2) where, by statute, enforceability is given to the agreement of the parties to submit a controversy to arbitration. Some statutes make enforceable only the arbitrators' awards while others make enforceable also the agreement to arbitrate. The agreement to arbitrate may be supplemented by rules, by-laws or other regulations of trade and commercial associations which require their members to arbitrate their differences, and for failure to do so such members may be fined, suspended, or disciplined by action of the organization. An agreement to arbitrate a future as well as an existing dispute is irrevocable and enforceable only under the United States Arbitration Act and under the recent laws of New York, New Jersey, Territory of Hawaii, Massachusetts, Pennsylvania, California, Oregon and Louisiana.

The common law rule of the right of a party to revoke the authority of the arbitrator prevails in the States of Alabama, Delaware, Maryland, Mississippi, New Mexico, Oklahoma, South Dakota and Vermont. In these States the only remedy the aggrieved party has is to sue for damages for breach of contract when the second party refuses to perform under an arbitration agreement. A party to a submission to arbitration of an existing

dispute may not revoke such an agreement in the following States: Illinois, Iowa, Maine, Michigan, Minnesota, Nebraska, Nevada, New Hampshire, North Carolina, Utah, Wisconsin and Wyoming, and also in Georgia after the submission has been delivered to the arbitrator, and in Missouri and North Dakota if hearings have been started. An agreement to submit to arbitration an existing dispute is irrevocable if the submission is made a rule of court prior to the rendering of an award in the following States: Arkansas, Connecticut, Florida, Idaho, Indiana, Kansas, Montana, Ohio, Rhode Island, Tennessee, Virginia and West Virginia, and in Kentucky when the submission states the issue and names the arbitrators. In Colorado and Washington the courts have held that an agreement to submit to arbitration a future dispute must be performed before an action at law may be commenced on the subject.

In January 1926, the United States Arbitration Act came into effect. Under this act a dispute arising out of a contract relating to interstate commerce in which more than \$3,000 is involved, or arising out of a maritime transaction, is arbitrable, and an agreement to arbitrate either an existing or a future dispute is valid, irrevocable and enforceable.

Practically all statutes in the United States make majority awards valid. While the practice still prevails of each party appointing an arbitrator, both to select an additional arbitrator, such additional arbitrator cannot alone render a valid award unless he is specifically authorized to do so by the parties. Under these statutes, except in the States of Massachusetts, Illinois, Nevada, Utah, Wyoming, North Carolina and to a more limited extent, Pennsylvania, questions of law can be referred to the court only upon the request or consent of both parties if any reference is allowed. Differences in the State statutes lead to different practices in different States and for this reason efforts are being made by business men and commercial and professional organizations to obtain a uniform State law applicable to all business controversies alike throughout the country.

The principles and practice embodied in the United States Arbitration Act and in the State statutes of New York, Massachusetts, New Jersey, Hawaii, Pennsylvania, California and Oregon, may be said to represent the commercial policy of the United States. Under these laws there are five outstanding principles: (1) A written arbitration agreement is valid and irrevocable save as any other contract is revocable, and specifically enforceable if made in accordance with the statute. (2) The agreement may be for either an existing or a future dispute. (3) The court, upon application of either party, is authorized to enforce the agreement, if necessary appointing an arbitrator. (4) The court will stay an action brought by a party to an arbitration agreement, pending its settlement by arbitration. (5) The award when confirmed by a court may have judgment entered upon it and is then enforceable in the same manner as any other judgment.

Tribunals.—As a result of these laws and the business use of arbitration thereunder in the United States, arbitration has become highly organized, requiring competent administration. New York city alone has more than 80 trade and commercial tribunals administered by various trades or commercial organizations. The American Arbitration Association, which is representative of the business, legal and professional arbitration interests of the country, maintains a national panel of arbitrators consisting of several thousand carefully selected persons distributed in different localities, so that throughout the country it is possible to arbitrate a dispute under standard rules compiled from the extended experience of the American Arbitration Association by men who are informed in arbitration principle and procedure.

At the beginning of 1928 the following branches of industry and commerce had adopted arbitration in some degree or form, to be administered through trade associations: the automobile industry, boot and shoe industry, bottlers' trade, clothing and dry goods trades, confectioners, construction industry, cotton and by-products, financial institutions, food industries, fuel, heat, light and power, furs, grain, hay and seeds, hardware, imports and exports, leather, hides and skins, lumber and allied industries, jewellers' trades, motion picture industry, paint, oil and varnish

industry, printing and engraving trades, real estate, rubber trade, silk industry, toy manufacturers, transportation, warehousing, wool and the theatrical industry. The aeronautical, electrical manufacturing, music, paper and pulp, chemical and zinc industries, furniture and florists' trades and the great retail organizations have the matter under consideration.

Approximately 75% of all commercial arbitrations in the United States are disposed of through trade associations, of which 332 have adopted rules and maintain facilities for their members. In addition, 162 trade associations provide occasional facilities and arrange for an informal procedure. The distinguishing features are that they deal with a given commodity, that they recognize trade customs in their consideration of the question and that the proceedings can be held locally and conducted uniformly by branches of associations in different parts of the country. Mixed cases are disposed of through local commercial bodies, such as chambers of commerce or boards of trade. In such instances, there is usually a supervisory committee, a panel of arbitrators and rules of procedure. Certain definite tendencies in policies are apparent: (1) toward uniform State arbitration laws which will make valid, irrevocable and enforceable either an existing or future definite agreement to arbitrate; (2) toward the use of arbitration clauses in contracts, safeguarding the parties against the unknown risks and costs of litigation; (3) toward the responsible administration of arbitration under rules of procedure; (4) toward the finding of awards in accordance with business customs and practice; (5) toward the submission of questions of law to the courts only when requested by both parties; (6) toward limiting arbitration to matters wherein the basis exists for making a business judgment; (7) toward the elimination of the umpire and the substitution of neutral arbitrators for the appointment of a partisan by each of the parties.

The increase in the practice and scope of arbitration in the United States is due to a number of causes, the most important being: (1) The increase in business makes it impossible for the courts to keep pace in the settlement of disputes. The fact that a legal decision is often long delayed has compelled business to adopt a more expeditious, cheaper and simpler method than litigation. (2) The changing provisions of the State laws, their liberal interpretation by the courts and the use of arbitration by attorneys on behalf of their clients greatly advance the practice of arbitration. (3) The desire of business to order its own affairs, to keep out of the courts and to avoid unnecessary publicity leads business men to settle their differences in private. (4) The educational work being carried on by such organizations as the American Bar Association, the Chamber of Commerce of the United States and local chambers, universities and trade associations, all working toward a common policy and practice, in co-operation with the American Arbitration Association—a central co-ordinating body—account for the direction now being given to arbitral policy and its development throughout the country. But most important is the realization that arbitration stabilizes an industry with respect to the relationships of its members, eradicates trade abuses, promotes ethical standards and increases trade through the elimination of friction and ill-will. These values, added to that of economy, are responsible for the extension of arbitration in the United States. (M. H. G.)

INDUSTRIAL RESEARCH: *see* RESEARCH, INDUSTRIAL. **INDUSTRIAL REVOLUTION, THE.** When we say of a society that it has passed through the industrial revolution we have in mind a definite picture of its life and power. We are thinking of a society that makes great use of machinery, conducts its operations in industry and commerce on a large scale, and supplies the needs of its simplest members by an elaborate series of world-wide exchanges. The creation of any such society must be in some respects a gradual development. Certain features of our modern economic life can be traced back to the days when Columbus and the great sailors of his time put Europe in touch with the New World and the Far East; others to the history of the Crusades, when a brisk trade was conducted by the chief Italian cities in the rich textiles of Syria; others to the earlier history of Europe when classical Greece, the successors of Alex-

ander the Great, and the Roman empire in turn exploited the wealth of the Mediterranean basin. There was large capital invested in industry as well as in commerce before the 18th century, and even so modern a phenomenon as mass-production was not altogether unknown before the industrial revolution. No people and no age could pass directly from a primitive and simple economy to a life so complicated as that of modern Britain or modern Germany. Some critics, surveying these earlier tendencies, doubt whether the term "industrial revolution" is appropriate, arguing that revolution implies sudden and catastrophic change. But a closer examination shows that the great inventions which distinguished the 18th and 19th centuries played so decisive a part in creating the new kind of society that the term industrial revolution, invented by a Frenchman and made familiar by Arnold Toynbee, is not too violent a description of the changes they produced. It is now an established phrase, like the Renaissance, or the middle ages, with a well-understood meaning and content.

England the Pioneer.—We mean, then, by the industrial revolution the change that transforms a people with peasant occupations and local markets into an industrial society with world-wide connections. This change has come to different peoples at different times. There are parts of the world, like China, where it did not begin till the 20th century began. It came first in England because the English people had favourable political institutions, internal free trade, advantages of climate and geographical position, considerable experience of foreign trading, special connections with the New World and abundance of coal. In the first phases of the revolution coal mattered much less than it did afterwards, for the first great mechanical inventions in the textile industries were worked by water-power, and rapid industrial development was possible at this stage without coal. This explains why France made such rapid progress as an industrial nation before the French Revolution. France had great inventors like Jacquard and Vaucanson, and she had a richer foreign trade than Great Britain. But when a series of inventions had made coal the chief source of economic power, France was at a great disadvantage. As late as 1847 she produced only 5,000,000 tons of coal, whereas the English production so early as 1800 was 10,000,000 tons, and from 1845 it was over 34,000,000. If France had kept the frontiers established by the Treaty of Amiens, her history would have been very different, for that treaty left her with the Belgian coal-fields.

The Revolution in Iron.—The inventions which gave this predominant importance to coal began with the discoveries by the two Abraham Darbys and by Henry Cort of methods of using coal instead of charcoal in blast furnaces and forges. Before these discoveries iron manufacture depended on charcoal. It was therefore carried on mainly in counties like Sussex with extensive woodlands. But by the early 18th century the industry was in great difficulties, for the supplies of fuel were giving out. When the Darbys, Cort, John Wilkinson and James Watt had revolutionized the industry the difficulties vanished, coal took the place of charcoal, and the iron manufacturer could set up his plant in the neighbourhood of coal-fields. So the industrial revolution created the black country, and enabled England to turn to account the good fortune which had given her abundance of coal, and coal conveniently placed near her ports. Between 1720 and 1788 the production of pig-iron in England grew from 25,000 to 68,000 tons; between 1788 and 1839 it grew from 68,000 to 1,347,000 tons.

The Textile Revolution.—The revolution in the manufacture of iron which created the black country was accompanied by a revolution in the textile industries which transformed Lancashire and the West Riding. This revolution was started by a series of inventions in the 18th century. The flying shuttle was invented by John Kay in 1733; the spinning jenny was patented by James Hargreaves in 1770; a roller spinning frame, worked by water-power was patented by Richard Arkwright in 1769 and 1775; the mule which enabled English mills to match the delicate muslins produced by Indian fingers was invented by Samuel Crompton in 1779. The cotton industry established by these discoveries was conducted at first by water-power, but before the

end of the century its progress and its power received a great stimulus from the most important of all the discoveries of the industrial revolution.

Steam Power.—Profiting by the earlier pioneer work of Thomas Savery and Thomas Newcomen, Watt learnt how to make steam the servant of man's will. By his invention of the separate condenser, patented in 1769, he produced a new type of engine. In his early engines steam was used to force a piston up and down, and they were mainly used for pumping water in mines, but Watt went on to devise a method by which steam could be applied to rotary movements as well, and this was in some respects the most important of his discoveries. From that time there was scarcely any limit to the range of the invention, which revolutionized one industry after another. In the textiles the new power was first applied to spinning; later it was used for weaving, as the result of a series of inventions, beginning with the imperfect power-loom patented by the Rev. Edmund Cartwright in 1785. The effect was to give new freedom to the industry, which was now independent of water-power, just as the iron industry was independent of woodland. The growth of the cotton industry was the most sensational event of the early revolution. In 1764 England imported 4,000,000 lb. of cotton wool, in 1833 she imported 300,000,000 pounds. A table drawn up by the Chamber of Commerce at Mulhouse in 1835 shows that in that year England produced over 60% of the cotton goods consumed in the world; France 16%; the United States 7%; Switzerland, Saxony, Prussia and Belgium between them a little less.

This expansion of the industry involved, of course, a great increase in the demand for raw cotton. When first the industry began to grow England and France competed for a deficient supply. At that time the West Indian islands provided more cotton than the continent of America. The United States had a great deal of short stapled cotton, which could not be exported profitably, because the cotton adhered so closely to the seeds that it was difficult and costly to prepare it for export. But in 1793 Eli Whitney invented a saw-gin which enabled this cotton to be cleansed, and from that time the United States became the chief source of supply. This invention led incidentally to a great extension of slavery in the southern States, for slaves were especially suitable for growing cotton in the river beds.

The woollen and worsted industries were older than the cotton industry, and in their case these technical improvements were introduced more gradually. They led to the concentration of both industries in the West Riding, the worsted industry declining in the eastern counties, and the woollen in the south-west.

Canals.—It is important to notice that the cotton industry was established on a large scale while England was still depending on canals and roads for transport. There had been a great development of road making and canal making in the 18th century, in consequence, partly, of the agrarian revolution. This revolution, which increased rapidly the system of large tenant farming, with landlords applying their capital to improvement, made farming much more productive. It was effected partly by Enclosure Acts which were passed through parliament, setting up commissioners to enclose the common fields and the common wastes. Under the old system individual freedom was limited by the rights of the commoners. By this change enterprising landlords could apply the lessons taught by Jethro Tull and other agricultural pioneers, who had discovered how to improve crops and stock. But the roads were in a very bad state, much worse than in contemporary France, and it was necessary to construct new roads and reconstruct old ones, in order to enable corn and other agricultural products to be taken to the towns. So the governing class threw itself into road development, and turnpike trusts were set up all over the country for that purpose. Similar motives led to canal building. The most famous of the inventors in this field was James Brindley, who was commissioned by the duke of Bridgewater to make a canal to connect his coal-field with Manchester. His success gave a stimulus to the movement, and the industrial districts of the north and the midlands were rapidly connected with each other and with the ports by a network of waterways.

Railways.—But man's new servant, steam, was soon brought

into use for the purpose of transport. The first steam locomotive was tried at the Merthyr Tydfyl iron works in the early days of the 19th century. The founder of the British railway system was George Stephenson, the engineer of the Stockton and Darlington railway, opened in 1825, and the designer of the engine which won the prize in the competition held at Rainhill in 1829. The success of the Liverpool and Manchester railway opened in 1830 led to an age of feverish activity in railway building, and by 1848 nearly 5,000 m. of railway line had been laid in Great Britain. This in its turn had a powerful influence on the metal industries. Sea transport changed more slowly; the first steamship crossed the Atlantic in 1819, and, by 1847, 60 or 70 steamships were turned out every year.

Engineering.—In some respects the most important of the results of Watt's discoveries was the use of machines for making machines. Mechanical engineering begins to be important in English history about 1820 (the first textile machinery was made of wood), and with the rapidly growing demand for machinery from all parts of the world its importance grew at a rapid rate. The scope and power of the industry were increased by a series of inventions such as James Nasmyth's steam hammer in 1838, and by discoveries associated with the names of Henry Bessemer (1856), the brothers Siemens (1866) and Snelus (1879), which created the modern steel manufacture. All the metal industries were helped further by the chemical discoveries of which Michael Faraday had made a beginning in 1826, discoveries that created in their turn the successful chemical industries of Lancashire and Cheshire.

The effect of all this energy in scientific pursuits and industrial enterprises was to make England the leading representative of the new civilization: the workshop of the world. Her early progress was all important. For, as we have seen, England had an industrial revolution before the railway era. In the two countries where industrial expansion was most rapid in the latter half of the 19th century, Germany and the United States, the industrial revolution began with the introduction of the railway. In earlier ages the chief obstacle to industrial development was the difficulty of land transport. In Germany and America this difficulty was resolved by the railways. In England, on the other hand, where the sea was nowhere very far distant, an industrial revolution was possible without the railways, because canals and roads could give access to the ports. It was mechanical engineering that received the greatest stimulus from the railways. Therefore, when the world wanted railways and docks, England was ready with the plant, the experience, the capital and the skill. Hence it was to English capital and English labour that the world turned for this task. But there was this difference between the early days of the revolution, when England sold piece goods all over the world, and the later, when she sold railways; for the railways she sold were turning peasant into industrial societies, and it was certain that when this change had taken place, England's preponderant share in the trade of the world would decline. When the 20th century opened England had powerful industrial rivals both in and out of Europe.

Electricity.—The 19th century was the century of steam. Before its close man had discovered in electricity an even more valuable servant. A new industrial revolution was thus set in train, a revolution of which we cannot yet forecast the consequences. One effect is seen in the growth of motor industries in the home counties. The great industrial revolution concentrated industry in certain districts; Lancashire is the home of cotton, the West Riding of wool, Staffordshire of pottery, the great metal industries are found near the coal-fields. Electricity gives industry again a wider choice, and the factory inspectors' reports for 1926 drew attention to the development of industries in the south of England. Transport is easier, and power can be made available in the country districts.

Social Results.—The conversion of a peasant to an industrial society brings with it great changes in a nation's habits and manner of life. Of the changes that followed the first development of the new system, those that made the greatest impression on the thinkers and observers of the time were the great improve-

ment in production, and the opportunities this new world offered to individual talent and character. The great cheapening of commodities was illustrated in one of the publications of the Society for the Diffusion of Useful Knowledge, by the case of stockings. This little book, *The Results of Machinery*, put it thus: "Two centuries ago, not one person in a thousand wore stockings; one century ago, not one person in five hundred wore them; now, not one person in a thousand is without them." Life was in this sense easier, and the first impression made by this improvement led to a belief that the secret of progress was to allow every enterprising person to make what profit he could by any means that he chose. There was another way in which the early results of the revolution made enlightened persons suspicious of any attempt to interfere with industry, or to control and direct the social life of the times. The revolution gave great opportunities to the workman who could save a little money and was shrewd and daring in investing it. Most of the early cotton spinners were men who had made their way. It might have been expected that the new industrial capitalists would come from the class of merchant capitalists who financed the woollen industry, but in fact they came from men of small beginnings. Robert Owen, for example, one of the most successful of them, owed his success to a loan of £100. The exhilarating atmosphere of a world in which men could make their own careers helps to explain the optimism of the time, and the disregard of evils which called for action.

Evils of the New Town Life.—For the industrial revolution had produced mischief of which the consequences still pursued the British people in the 20th century. That revolution found Great Britain without any effective system of local government. The country districts were in the hands of the country gentlemen, acting as magistrates, and the towns were unorganized for any of the more important purposes of administration. Manchester, which had a population of a quarter of a million, was at the time of the Reform bill administratively a collection of villages governed by a court leet. It is not surprising, therefore, that the towns which sprang up so rapidly, as the textile and metal industries expanded, were quite unable to handle the new problems, and that their uncontrolled growth made the new town life hideous and squalid. In the 'forties, when parliament had been reformed, and a spirit of enquiry was active the state of the towns was examined by committees and commissions, such as the Health of Towns Commission, and their appalling condition was revealed. A first effort to reform those conditions was made by the Public Health Act of 1848, but the problem proved too difficult, and the several attempts that were made in the 19th century showed how fatal was the mischief done in the early days when there was no legislation to cope with the new conditions.

The Regulation of Factories.—The revolution had made this problem of town life acute and pressing. It created also new industrial relationships which soon caused strife and discontent. Before the textile industries passed into the factory, spinning and weaving were done either in the workers' homes or in the house of a small master. Spinning was woman's work and weaving man's work. In the mill, spinning was mainly men's work and weaving women's work, but both weavers and spinners depended on the help of children. The early mills had difficulty in getting labour, for they were built on streams in districts where there was little population. The difficulty was got over by the supply of children from the workhouses. The hardships of these children led to an agitation and it was made illegal to apprentice children 40 m. from home. But by this time the use of steam-power had made it possible to put up factories in or near towns, and the apprentice children were no longer needed. The campaign against the long hours of children became a campaign against the long hours of the factory, for it proved in practice impossible to shorten the hours of children without restricting the hours of the factory, and this campaign was brought to success in 1847, when parliament passed the Ten Hours Act, for which Shaftesbury (then Lord Ashley) had fought since 1833. Factory legislation and factory inspection were gradually extended to other industries in the course of the century. In this department of government England has led the way.

Trade Unions.—Large-scale industry in engineering and mining as well as in the factory created a different relationship between employer and employed than the sort of relationship which existed in the days of the craftsman. The place of the guild was taken by combinations of employers and employed. Strikes and combinations were not unknown before the industrial revolution, but the revolution gave a new importance and a new scope to trade unions. Their rights and their liabilities became one of the acute questions of politics. A fierce act against trade unions, called the Combination Act, was passed in 1799, modified in 1800, and repealed in 1824. Next year a new act defined the powers of the trade unions in such a way as to make effective combination very difficult. Trade unions did not obtain full recognition until after the workmen had been enfranchised in 1867. After the World War they were given a new place in public life by the institution of Whitley councils and similar bodies, composed of representatives of organizations of employers and workpeople.

Unemployment.—Another result of the industrial revolution was periodic mass-unemployment, a consequence of mass-production. The revolution made industries interdependent, and by bringing the whole world into close economic relationships it made the industries of one country dependent on the conditions in remote places. A coal strike hits the textile industries; a deadlock in engineering holds up shipbuilding. The poverty or the quarrels of the Continent affect all British export industries; a political or commercial crisis in America may throw the cotton industry of Lancashire or the engineering industries of Newcastle into distress. Unemployment was not a new thing at the industrial revolution, but it is evident that a nation which is involved in this world economy is subject to vicissitudes that do not affect a more primitive community. It is sometimes said that the industrial revolution has substituted unemployment for famine as the nightmare of mankind.

Problems of Industrial Civilization.—The industrial revolution has not had exactly the same consequences in all countries. For those consequences depended partly on the conditions preceding the revolution and those conditions varied. English experience has been peculiar in one important respect. In England peasant farming disappeared with the agrarian revolution that began in the 16th century and ended in the 19th century. In other countries the peasant survived. France, for example, possesses important industries, but her people are mainly rural. Germany, much more industrial than France, has still a large peasant population. In England the old peasant type of life, in which agriculture and village crafts were combined, has vanished, whereas something of it remains in other countries that have passed through the industrial revolution.

But the industrial revolution has produced certain results that are common to industrial civilization. Thus one country after another has been obliged to copy the example of England and to legislate for the control of factories. Asia has followed Europe. Provision against unemployment by State or municipal insurance was first made in certain Continental countries, notably Germany and Belgium. Just before the war England established a scheme for a few industries, and after the war this scheme was extended to cover almost every industry except agriculture. In almost every industrial country this problem has received attention. If we want to realize how much the industrial revolution has done to create common problems and to suggest common remedies we have only to glance at the publications of the International Labour Office of the League of Nations, or to consider what reforms it pursues by conference and convention. In every country the same problems and the same remedies are under discussion: unemployment insurance, factory acts, hours of work, minimum rates of wages, the rights of trade unions, family endowment. One effect of the all-embracing system which the revolution has established has been to standardize the occupations, the cares and even the amusements of man. The cinema is as much the mark of the modern world as the factory; the railway as the football or baseball field; the wireless talk as the trade union. It is by these institutions that the modern traveller is reminded, as the mediaeval traveller was reminded by cathedrals and monasteries, that he

can leave his own country without passing into a wholly strange and separate world.

INDUSTRIAL SCHOOL (in Great Britain) a school for the education and vocational training of neglected or delinquent children, under 14 and generally under 12 years of age when they are sent there by a court. A child may be committed to an industrial school for such period as the court thinks proper, but not beyond the age of 16. The word was formerly used in the United States in the same sense, but has died out of late. See also REFORMATORY SCHOOLS.

INDUSTRIAL TRANSFERENCE. In the normal course of industrial development the decline of particular industries (or, as has more frequently happened, of particular crafts) occurs gradually, and the adjustment of the personnel of the trade or craft to its reduced demand for labour accomplishes itself, without mass distress, through such natural processes as the retirement or death of its ageing workers, the reluctance of youths to enter a declining trade where working conditions are bad and prospects worse, and the continuous voluntary exodus from the industry of persons of all ages attracted by the better conditions prevailing and prospects offered in other industries in the neighbourhood or, maybe, in another part of the country, or of the world. This organic readjustment has not always taken place in such rapid and thorough fashion as to provide against any and all cases of individuals or communities being left stranded by the receding of their craft, but for at least a century and a half prior to the close of the World War the development of trade, commerce and industry was such as to create an absorptive power which in good time drew sufficient surplus labour from the declining industries or areas to reduce the position there to locally manageable proportions. After the armistice, however, British industry found itself in a position in which the decline of certain industries from their pre-war or swollen post-war dimensions was so rapid, and the expansion of other industries needing increased numbers of workpeople so halting, that large numbers of individuals skilled in particular crafts, and large blocks of the industrial population located in depressed areas, were left for several years in a chronic state of under-employment for which the internal readjustment of the industrial organism provided no escape. It was the coal, iron and steel, engineering, shipbuilding, and, later, the cotton and woollen and some other staple industries which were found, as the post-war wave of prosperity subsided, to have workers in excess of their capacity for employment.

On the other hand certain industries and certain areas of Great Britain were enjoying an expansion and activity comparable with that of any good pre-war year. The south-eastern half of the kingdom was much more prosperous than the north-western half. There were industries—such as those in the chemical group, some branches of the textile trade, the clothing trade, the printing trades, etc., whose rate for unemployment was round about 5 per cent. and in some cases as low as 3 per cent. There were whole counties in which the rate of unemployment was less than 3 per cent. Experience over the previous few years had shown that surplus workers in the depressed areas and industries could, given favourable opportunity, find work in the more thriving areas and it seemed probable that with encouragement, guidance and assistance the rate of this movement could be increased. But the employment exchange system was not cut out to move large groups of workpeople with their families from one part of the kingdom to another. One of the difficulties in the way of the transference of long-unemployed workers was the petty debt to tradesmen, and perhaps to the local authorities, incurred by the family whose head was unemployed; another was the scarcity of houses, especially in the parts where employment was brisk. In these circumstances the Government announced on Jan. 6, 1928 the estab-

lishment of an Industrial Transference Board "for the purpose of facilitating the transfer of workers, and in particular of miners, for whom opportunities of employment in their own district or occupation are no longer available."

See House of Commons Official Report Dec. 7, 1927. (J. H.)

INDUSTRIAL WELFARE AND MEDICINE, a term used in Great Britain to embrace not only the activities of industrial medical services but the control of environment and working conditions; the study of the effects of poisons and other occupational health hazards and the investigation of the mortality and morbidity experience of occupational groups. In the United States the work is called industrial hygiene. The subject is treated here in two sections: A. *Great Britain* and B. *The United States*.

GREAT BRITAIN

Industrial Welfare.—The movement, which was only embryonic before the World War, received great impetus in Great Britain from the recommendations of the Health of Munition Workers' Committee. The work includes needs within and outside the factory. Within the factory it covers the selection of workers for engagement; supervision of general behaviour; of progress and apprenticeship; of transfer and disposal of workers; of general cleanliness, ventilation and temperature; of canteens; of ambulances, rest-rooms and first-aid; of cloak-rooms, sanitary conveniences and of overalls. Outside the factory it covers housing accommodation, transit facilities, sick visiting, recreation and education. The keeping and studying of personal records of earnings, sickness and accidents is required. Welfare committees composed of workers are found invaluable to the activities of welfare superintendents.

The Home Office obtained powers under the Police, Factories, etc. Act 1916, enabling the Secretary of State by order to require occupiers of factories to make reasonable provisions relating to "arrangements for preparing or heating and taking meals; the supply of drinking water; the supply of protective clothing; ambulance and first-aid arrangements; the supply and use of seats in workrooms; facilities for washing; accommodation for clothing; arrangements for supervision of workers." Under these powers more than 14 orders had been made by the beginning of 1928 concerned with the special needs of different industries. At the same time a series of valuable pamphlets have been issued to set forth how the requirements of the orders can be complied with. Action on these lines continues; but already some matters have become of general application, thus drinking water must now be supplied in all factories, while the provision of first-aid has become generally compulsory under the Workmen's Compensation Act 1923.

Other activities which may be called "voluntary" welfare include housing efforts, recreation grounds, institutes, educational schemes, nurses and sick visiting, canteens and dental clinics at factories; all provide examples of extension of factory welfare without legal compulsion.

In 1872 the Metalliferous Mines Regulation Act called for accommodation for persons employed in metalliferous mines to dry conveniently and change their clothes. In 1910 the Mines Accidents (Rescue and Aid) Act gave power to make orders relating to: (a) The supply and maintenance of appliances for use in rescue work, and the formation and training of rescue brigades; (b) The supply and maintenance of ambulance appliances and the training of men in ambulance work.

The Coal Mines Act of 1911 contained, too, an important clause providing for accommodation and facilities for taking baths and drying clothes where the majority of workmen employed in a mine desire such. Unfortunately this clause was a dead letter except at some half-dozen collieries. But under the Mining Industry Act 1920, welfare work for miners received a great impetus. This Act provides a fund, derived from a levy of 1d. a ton on the output of each mine every year, to be applied for purposes connected with social well-being, recreation and conditions of living of workers, and with mining education and research.

The fund amounts to about £1,000,000 a year; its allocation is directed by an independent central committee on which both min-

ers and colliery owners are represented. Four-fifths of the contributions coming from each coal-field must be spent within that field: the remaining one-fifth of the fund is devoted to welfare matters of mutual interest to the whole industry, such as the promotion of research into safety and health, and the provision of higher education for miners and their families. Expenditure from the fund is now year by year keeping pace with contributions. The Act of 1920 was due to expire in 1925, but the success achieved by the activities thus instigated led to prolongation of the life of the levy to the fund for a further period of five years. The total credits of the fund on Dec. 31, 1928, amounted to £7,883,105.

The provision of pithead baths has been insured by part III. of the Mining Industry Act 1926, which placed a levy on royalties, "the royalties welfare levy." The sum so raised is made over to the central Welfare committee to be devoted to the provision of pithead baths.

The central committee consults with district committees concerning the amount and purposes of grants in each district. The activities of the fund (with the one exception of allocations for pithead baths) deal with needs *outside* working hours; while progress in factory welfare made under statutory orders is extending with regard to needs *within* working hours. The contrast is sharp.

In the case of factories voluntary effort is forwarding outside welfare schemes; but in the mines no similar efforts are taking place with regard to such needed inside welfare as the provision of drinking water, improved lighting, or pithead kitchens.

The procedure followed in these two lines of advance is also in contrast. Factory welfare proceeds through statutory orders, compliance with which can be enforced; while mining welfare consists of activities, originated and pursued by the mining community, but financed through a statutory levy.

Industrial Fatigue.—The maintenance of health, especially that of women and young persons, has always been a driving force in the code of legislation controlling factories and mines, but its close study is practically a new science, known technically as the study of industrial fatigue. In Great Britain the study is pursued on general principles by the Industrial Fatigue Research board, an integral part of the Medical Research council. This board came into existence in 1918, owing to appreciation of a national need for intensive investigation to which attention was directed during the War by the activities of the Health of Munition Workers' Committee. Problems of interest to particular establishments are tackled by the National Institute of Industrial Psychology (*see* INDUSTRIAL PSYCHOLOGY). Much practical knowledge as to human activity, embodied in some 50 reports issued by the board, and in the Journal of the Institute, has been placed on a scientific basis.

Certain points may be succinctly stated: work is necessary to health, and health is needed for efficient work; even, steady work is better than spasmodic efforts; an optimum temperature, which should vary about a mean, exists for each process and is associated with best output, least sickness and fewest accidents; ventilation is to be read in the stimulating effect of air movement, rather than in change of air; rest periods during long spells of work, particularly if posture is changed, may increase output and lessen monotony; monotony in repetitive work, in temperature, in ventilation, in long spells of activity without pauses, and even in food supply, is disadvantageous; good factory canteens improve health and output; change of personnel; *i.e.*, labour turnover, reduces production and increases lost time due to sickness and accident; suitable overalls create pride in work and in person; vocational training adds joy to work; vocational selection on engagement increases output and reduces labour turnover; certain workers exhibit a predisposition to sustain accidents and should be employed where accident-risk is at a minimum; the tendency to sustain accidents is associated with a tendency to fall sick.

Industrial Medicine.—This deals with the prevention of sickness and the restoration to health of the disabled. Modern research has enabled important protective measures to be adopted, and established the tremendous importance of personal, as contrasted with mechanical, factors; they account for 80% of industrial acci-

dents. Further, just as in the case of sickness, the newly employed and those who are not quite well are disposed to sustain accidents. Action should, therefore, aim at interesting workers in accident prevention through the safety-first movement (*see SAFETY FIRST*), at reducing labour turnover, at maintaining health, and at eliminating the susceptible. Under the heading of accidents are here included sudden gasings; e.g., from carbon monoxide, nitrous fumes and arseniuretted hydrogen, as well as caisson disease.

Information as to the occurrence of certain occupational diseases; e.g., anthrax, toxic jaundice, chrome and epitheliomatous ulcerations, and poisoning from lead, mercury and arsenic, is obtained from notification sent by practitioners to the chief inspector of factories.

Compensation claims for diseases named in the schedule to the Workmen's Compensation Act 1906 give information concerning the occurrence of other diseases, of which certain troubles which particularly concern coal-miners are the most important; i.e., nystagmus, and miners' beat knee, beat hand and beat elbow. Here recent investigation into causation is ahead of prevention; thus, the distressing trouble, nystagmus is associated with work for long periods in imperfectly lighted galleries of coal-mines. Owing, however, to the danger of explosions from mine-gases, the problem of improving the lighting underground is not a simple one (*see COAL; MINING*).

In contrast stands another compensatable eye trouble, cataract, which occurs among glass blowers and furnacemen exposed to glowing heat. Here means for prevention are known; they consist in wearing spectacles, the glass of which has been specially devised for cutting off heat rays, but difficulty arises in getting the workers to use them.

Further knowledge is drawn from occupational mortality records. They reveal any undue prevalence among a group or groups of workers of some particular cause of death; phthisis is the most notable example (*see TUBERCULOSIS*). Recent statistical investigation has shown that when this cause of death (a) is the only one in excess, its undue prevalence is due to the spread of infection among persons whose daily work brings them close together; e.g., in tailoring, printing, and making boots and shoes; (b) is associated with excessive death-rates from other lung diseases, and occurs later in life than usual, as happens among sandstone masons, gold-miners, tin-miners, grinders of metal, some pottery workers and others, its excessive prevalence is due to inhaling fine dust of silica, which sets up a condition in the lungs known as silicosis, a condition which takes some years to develop and predisposes its victims to tuberculous infection; and (c) is associated with excessive death-rates from all other causes of death, and occurs rather earlier in life than usual, as happens among publicans and inn-servants, its undue prevalence is caused by excessive indulgence in alcohol.

Knowledge of causation in each case points the way to prevention: (a) Commodious, well ventilated and lighted premises, associated with medical examination to eliminate the tuberculous, will rid tailoring, printing and shoe-making from the scourge of phthisis. (b) Reduction to a minimum of risk from breathing silica dust must abolish silicosis; the problem now belongs to the technical engineer and is being solved in certain industries. The financial burden of compensation is promoting active attention to dust prevention and control. (c) Limitation of alcohol consumption, such as has been taking place in this country in recent years, and could be extended, has already reacted not only upon the occurrence of phthisis in industry, but also of ill health from other causes, including accidents.

Another disease to which mortality records have directed attention is occupational cancer (*see CANCER*). Workers who handle pitch, a distillation product of gas-tar, and others who mix pitch with coal-dust in the manufacture of briquettes, suffer from warts which appear on the exposed parts of the skin, and also on the scrotum. These warts show a special tendency to become epitheliomatous with the formation of "pitch" cancer. Shale-oil workers coming in contact with crude paraffin, a product obtained by distillation, similarly suffer from warts and "paraffin" cancer; but workers manipulating refined paraffin do not suffer. Chimney-

sweeps have long been noted for their high death-rate from scrotal cancer which originates from exposure to soot, a distillation product of coal. Quite recently an equally high mortality from scrotal cancer has been revealed among mule-spinners in the cotton trade due to contact with lubricating oils, possibly obtained from shale. Cancer of the lips and buccal cavity is nearly confined to males who by smoking expose these parts to the distillation products of tobacco. The evidence here summarized suggests that certain products obtained by distilling vegetable substances can sensitize the skin to cancer.

Evidence from the dye industry suggests that the products in question may possibly be benzene compounds. Workers in this industry exposed to certain amino-benzene compounds, particularly benzidine and naphthylamine (compounds which, when they gain access to the body, are excreted by the kidneys), have been found to develop malignant tumours of the bladder.

Treatment during the early stages of illness and injuries sustained in occupation is not peculiar to industrial medicine, even though recent advances in orthopaedic surgery have been of great benefit to those manually employed. But in a few cases treatment is special to the disease; e.g., the onset of caisson disease can be met by immediately resubmitting the victim to the high pressure atmosphere from which he has just too rapidly emerged; or, again, persons overcome by carbon monoxide gas can be best brought round by the new method of administering a mixture of oxygen and carbon dioxide through artificial respiration; while burns caused by acids or alkalis, which must be specially neutralized before ordinary treatment is applied, may be added to the list.

The convalescent stage on the contrary may be profoundly expedited by occupation, particularly where recovery is slow and tedious. The industrial convalescent tends either to return to work too soon before he is ready for full employment, when he may quickly break down again, or, by saving himself, develop bad habits; or to delay—particularly if he is receiving compensation—until he has lost skill, developed some permanent stiffness, or become neurasthenic. He needs, at an early stage, amusement to divert his thoughts; next, occupational therapy, in which work is performed for wages during limited hours, in order to occupy his mind and assist in restoring lost or weakened function; e.g., a hand stiff after a wound; or lastly, vocational training for new work when he cannot return to his previous occupation.

At each stage industry can play its part, but with regard to occupational therapy and training it is the only available agency. "After-care" in workshops, and special settlements for those discharged from tuberculosis sanatoria is pointing the way, which is equally valuable for orthopaedic, mental and other cases. Occupational therapy and vocational training are rapidly coming to the front both in Great Britain and America.

THE UNITED STATES

Though the specific occupational diseases are numerous, a relatively small part of the sickness of working persons is due to such ailments. Apart from such disabilities as those due to faulty posture and inadequate or defective illumination, most of the

possible ill effects of work and working environment obviously must be exerted upon the body or through entrance to the body by way of the skin, nose or mouth.

Dust, Fumes and Gases.—With little doubt, the most important single occupational health hazard is atmospheric pollution by toxic or irritant dusts, fumes and gases. Most of the industrial poisons are air borne and through inhalation reach the lungs, while certain ones are in part swallowed and thus exert their effects through the gastro-intestinal tract. Most dusts are made up of units of a wide range of sizes, from fragments readily discernible by the unaided eye, to microscopic particles measured in fractions of a micron. Probably one-half of the dust inhaled is exhaled; a large portion of the remainder is caught by the moist mucous membranes of the upper respiratory tract, the nose and throat. Some is trapped on the walls of the larger tubes leading to the lungs and much of this is driven back toward the throat and is eliminated with mucous secretion. Only the very small dust particles, those approximately 10 microns or less in diameter, can penetrate far into the lungs. Dusts made up of fine particles may not be readily visible. They can be present even in a damp atmosphere.

Not all dust is notably harmful, nor all harmful dusts equally dangerous. Certain dusts are injurious because they are definitely poisonous. Others cause a disease of the lungs known as pneumoconiosis. Generally speaking, inorganic dusts, as those of metals or minerals, do more damage than organic dusts, as vegetable or animal matter. Not infrequently, dusts are of mixed character, inorganic dust being mingled with organic, as for example, the dust of jute or flax mills where earth or sand (inorganic) may be present in considerable quantities mixed with vegetable (organic) particles.

By far the most important of the injurious dusts is silica (an oxide of silicon) which is the major constituent of sand, quartz and granite. It produces a form of pneumoconiosis known as silicosis, characterized by a growth of fibrous tissue in the lungs accompanied by gradual loss of normal lung function and usually, ultimately, is associated with the development of pulmonary tuberculosis. (See MINERS' PHTHISIS.)

Poisons cause perhaps the most clearly defined group of occupational diseases. The rapid progress of industrial chemistry has led to the introduction of many substances known to be toxic, while new processes are constantly being developed bringing, not infrequently, new hazards in the exposure of workmen to poisonous substances.

Lead is used in most paints, in floor coverings, in many sorts of glass, commonly in brass and in solder; in plumbing installations, in the storage batteries which furnish power or light for motor cars, railroads and aeroplanes, in the rubber of tires and in much of that used for other purposes, in modern high compression gasoline, in the type and plates from which books and newspapers are printed and in scores of other articles of common use. Inevitably, the men and women who produce, use or market many of the articles containing lead may be affected by this very toxic substance. Reports of deaths attributed to lead have declined relatively in recent years, but such reports do not accurately reflect the actual influence of lead poisoning. There is abundant evidence that lead reaching the lungs is more readily toxic than that ingested. Some individuals are extraordinarily susceptible to poisoning and when exposed for even a few days to considerable quantities of lead may be seriously affected. True acute poisoning is very rare. Most of the cases of chronic type recognized have been exposed to lead over a period of months or years. Death may be due directly to severe poisoning, but in most cases is in part attributable to other causes, with lead as a secondary factor. The disease admits of prevention and control.

It is quite impracticable to list all of the recognized industrial poisons, which number several hundred. The most important are lead and its derivatives, benzol and many of its derivatives and carbon monoxide. There are others scarcely less important, such as mercury, arsenic and hydrogen sulphide (*q.v.*).

Skin Affections form a very large and important group of occupational diseases involving a multitude of industries and pro-

cesses. A list of skin irritants would be almost as long as that of the industrial poisons. Prominent, however, among the industrial dermatoses are the superficial cancers produced by coal tar, soot and a number of petroleum products (see DANGEROUS TRADES), chrome sores, a great variety of burns by powerful acids and alkalies, the dermatitis of candy workers and chocolate dippers, that of masons and plasterers and the folliculitis or infection of the hair follicles of the arms common among machinists. The causes of the many industrial skin diseases are so diverse, the conditions differ so greatly and so many simulate dermatoses of non-industrial origin that most cases call for the investigation and care of a dermatologist.

Ventilation.—Wholly apart from risks of atmospheric poisons, of increased or diminished atmospheric pressure and of extremes of temperature and humidity, good working conditions entail proper ventilation. The criteria of good ventilation are that air should be (1) pure rather than polluted by dust or other foreign matter, (2) cool rather than warm, (3) moist rather than dry and (4) moving rather than still.

In the United States work rooms tend to be too warm. A temperature of approximately 68° F is sufficiently high for persons engaged in sedentary or very light work and too high for those engaged in more active exertion. At 68° F the relative humidity for sedentary work should be about 45%.

Light.—A great part of the work men and women perform under modern conditions must be done in buildings dependent for light upon sources other than the sun. The aspects of industrial lighting which warrant particular consideration are its character, its adequacy and the location of the source in relation to the eyes of the worker.

Apart from the question of general or focal illumination of work, a discussion of light involves consideration of the hazard of such light rays as the ultra-violet rays and of the kindred rays known as Roentgen rays or X-rays and those emanating from radium. Ultra-violet rays given off in arc welding, in arc flashes on electric switchboards and from various other sources, may produce a very distressing dermatitis or ophthalmia, the latter a congestive reaction of the conjunctivae or lining membranes about the eye. Workers with X-rays and radium or with certain other radio-active substances may develop a severe dermatitis or even cancer of the skin. In recent years numbers of workers with radio-active earths have suffered injury or even death due to the destructive action of the gamma rays of radium upon the blood-forming organs and upon other tissues.

Industrial Medical Service.—The mutual interest of employer and employed in the maintenance of the health of workers has led to the establishment in the United States of hundreds, perhaps thousands, of industrial and mercantile health services, varying greatly in purpose, in degree of elaboration and in standards of professional service, but all contributing in some measure toward the furthering of the physical well being of the working men and women who utilize them. Many of the industrial medical activities found their origin in an effort to meet the need for furnishing the prompt and adequate medical care demanded of employers by the operation of workmen's compensation acts which most of the several State legislatures passed between 1912 and 1920. Many of the industrial clinics, dispensaries or plant hospitals continue to limit their activities largely to emergency surgery. There is, however, rapidly spreading a realization of the fact that sickness is more important as a cause of working incapacity than are accidents, that from five to ten days are lost from work on account of illness for one lost from injuries, and that economic self-interest, if not humanity, calls for intelligent consideration of the ill health of workers and of means for its prevention or remedy.

The most simple effort to meet the medical needs of industrial workers lies in the provision of the "first-aid kits" found in most industrial establishments throughout the country. From this elemental installation, plant medical services range far in complexity of organization. In many industrial dispensaries a trained, registered nurse is on duty the full working day, who usually works under the direction of a part-time or full-time physician.

Few full-time physicians are engaged in plants employing less than a thousand, but many such plants employ part-time physicians. In larger establishments a reasonable ratio for adequate health protection is one physician to every 2,000 employees and one nurse to every 1,000.

Where plant medical departments serve a large organization the variety of activities may include certain or all of the following: Physical examination of labour applicants and the subsequent periodic examination of employees; re-examination of individuals transferred from one department to another; emergency treatment of minor injuries and illnesses; diagnostic aid in involved and obscure clinical conditions with guidance in the seeking of further medical counsel and care and a well-trained and competent visiting nurse service.

In addition, there may be an eye clinic for the treatment of eye injuries and diseases as well as for refraction; dental clinics for the examination of the teeth of labour applicants and for the supervision of the dental hygiene of employees; psychiatric clinics for the study and guidance of cases of mental abnormality; physiotherapy units with facilities for the care of such cases as old fractures, burns, bruises, sprains and arthritis, by baking, massage or diathermy; posture clinics for the correction of gross postural defects; and nutrition clinics offering supplementary diet for cases of malnutrition or underweight.

A few establishments maintain sanatorium facilities for tuberculous employees, either through a private institution or through the support of beds or cottages in semi-public sanatoria. Others conduct rest houses or camps for the use of debilitated employees. A few railroads or isolated groups operate excellent private hospitals. More frequently, industrial organizations maintain in local hospitals beds or wards, for the care of injured employees. In most instances these various services are conducted at the cost of management; in others, the cost is shared by employees, perhaps through a mutual benefit association.

The prime purpose of these varied industrial medical activities is not to replace or supplant the personal physicians of employees, but rather to meet emergency needs without loss of working time, production and wages; to stimulate an intelligent interest in the maintenance of health and to offer guidance in the efforts of sick or defective individuals seeking competent medical care at prices they can afford to pay. Through the study of the clinical records of the all too small portion of plant medical departments which keep trustworthy and accurate records, there is coming to light knowledge of the nature and extent of sickness among the great portion of the population engaged in industries. Industrial morbidity data are of such great value as to justify almost alone the cost of plant medical service.

The Governmental Control of industrial and mercantile working conditions is not uniform throughout the States. In most of the larger industrial States, departments of labour or industrial commissions maintain inspection forces and issue regulations for the suppression of unhealthful conditions and the encouragement of safe practices in operation. Subsidiary or separate boards administer the workmen's compensation acts. But few State or territorial compensation laws assure compensation for any important number of cases of occupational disease. There is observable a very definite trend toward the inclusion of such diseases, and in a number of States, there are being developed better resources for guidance of industry in connection with the control of hazardous processes. A number of the larger municipal health departments have nominal organizations in the field of industrial hygiene. Generally speaking, their contribution is negligible beyond the realm of examination of food handlers. The U. S. Public Health Service, through its office of industrial hygiene, has for years made many notable contributions to the subject.

INDUSTRIAL WORKERS OF THE WORLD, THE, commonly known as the I.W.W., a revolutionary labour union organization which played in the early 20th century a considerable part in American and world labour history. It was founded in July 1905 at Chicago, Ill., as a result of a conference of Socialists and trade union leaders, of whom the most outstanding were E. V. Debs (*q.v.*), William D. Haywood, Daniel DeLeon, W. E. Trautmann, Vincent St. John and the Rev. T. J. Hagerty, who provided the first organizational plan of the union (known by Samuel Gompers' derisive nickname of "Father Hagerty's wheel of fortune"). All workers of every trade were to be accepted by the union which was, and is, subdivided into industrial sections (29 in number in 1928), craft unions not being allowed. The basis of the organization was explained in its well-known preamble. "The working class and the employing class have nothing in common. . . . Between these two classes a struggle must go on until the workers of the world organize as a class, take possession of the earth and the machinery of production and abolish the wage system." (This phrasing was adopted in 1908, a previous reference to political action being deleted, as a result of a struggle in which the syndicalist element thrust out the followers of DeLeon.) The organization was bitterly opposed to the American Federation of Labor (*q.v.*) on the ground of its alleged supineness in defending its members, its toleration of inter-union craft quarrels, and the anti-revolutionary attitude of its president, Samuel Gompers (*q.v.*).

Its chief strength, originally, lay in the Western Federation of Miners, which withdrew in 1907 on the unseating by the I.W.W. of President Sherman, its nominee. Since that time its strength has varied very greatly; the figures of paid-up membership in 1906 were 60,000 and in 1919 35,000, but these figures give no reliable indication of its strength. Since the defection of the miners, the I.W.W. membership has become more and more predominant among the nomadic workers (partly foreign born) such as lumber-men, long-shoremen and "hoboes," for whom the American Federation of Labor made no provision. This class of worker rarely pays dues, except on the occasion of first taking out an I.W.W. ticket. Of the innumerable strikes directed by the I.W.W. the Lawrence, Mass., strike of 1912 was the most famous and first brought the organization into prominence. Some 30,000 textile operatives were involved and for the first time large bodies of non-English-speaking workers were led together to ultimate victory; their spirits being kept up partly by the use of the I.W.W. "red book" songs, of a coarse but vigorous character, which have since travelled across the world. In addition, many "free speech fights" were undertaken, *e.g.*, in 1909 at Missoula, Mont., Spokane, Wash., Newcastle, Pa., and later more important struggles at Paterson, N.J., Aberdeen, S.D., Old Forge, Pa., San Pedro, Calif., etc. These were mostly cases in which the municipalities objected to I.W.W. propaganda and arrested the "wobbly" (the slang name for I.W.W.) speakers, the I.W.W. replying by providing a continuous stream of speakers "until the jails burst." Over 5,000 "wobblies" have been in prison. Elsewhere, especially in the western States, the history of the I.W.W. has been violent and sanguinary. The facts which led, for example, to the shooting of the organizer and poet, Joe Hill, in Utah, are greatly disputed; the murder of organizer Frank Little in Butte, Mont., has been dealt with in a Federal enquiry. (See the *Sixth Annual Report* of the Secretary of Labor.) In some of the States attempts were made to drive the I.W.W. out of existence.

After the World War, the general attack on "red" organizations, together with a quarrel with the Communist International (*q.v.*) gravely weakened the I.W.W. A large number of States have passed "criminal syndicalism" laws, mostly held constitutional on appeal to the Supreme Court, with the object of suppressing the I.W.W. altogether. A mass trial of over 100 prominent I.W.W. members at Chicago in Aug. 1918 resulted in a number of heavy sentences. The less important position of the I.W.W. since the War may be due to the cutting off by the immigration laws of the influx of unskilled labour which formed its most hopeful field. But it should be added that the I.W.W. claims to have had its highest recorded membership in 1923.

Australia.—I.W.W. locals exist, or have existed in nearly every industrial country, especially in the ports. In Great Britain they have appeared in London, Liverpool and Glasgow. But they have only achieved importance, outside America, in Australia between 1911, when the first local (Adelaide) was chartered from Chicago, and 1917-18, when the organization faded away.

See P. F. Brissenden, *History of the I.W.W.*, Columbia University Studies lxxxiii. (1920) with bibl.; V. G. Childe, *How Labour Governs in Australia*, ch. x.-xi. (1923). See also SYNDICALISM, SABOTAGE and DIRECT ACTION.

INDUSTRY, the quality of steady application to work, diligence; hence employment in some particular form of productive work, especially of manufacture; or a particular class of productive work itself, a trade or manufacture.

INDUSTRY AND TRADE, WAR CONTROL OF. Government control of industry has appeared sporadically in every important war of modern times, under the form of commandeering of supplies and means of transportation and production. It has also occasionally assumed the form of price-fixing. But, except in the rare cases of cities under siege, governmental control never assumed the form of a general system, dominating the whole economical life of a belligerent nation, before the World War of 1914-18. In that war the general control of industry was inaugurated promptly by Germany, after a considerable delay by France and England, and, after many half-way measures that proved ineffective, by the United States in the last year of the war. In the case of every belligerent nation the extension of control was a gradual process, which had by no means reached its logical limits when hostilities came to an end.

The conditions that forced control of industry upon the several warring nations were:—

1. Universal conscription, with its tendency to disorganize all industries, essential and unessential alike, by the withdrawal of the most energetic labourers and "key-men" in the technical and administrative staffs;
2. The vast consumption of material and equipment under the technical conditions of modern warfare;
3. The insatiate demand for financial resources for maintaining and supplying the huge armies in the field and the services incidental to them;
4. The maintenance of the health and spirit of the working civil population through the provision of the necessities of life at practicable prices.

While the conversion of national industry to the uses of war was nowhere complete, it is a conservative estimate that in all the chief belligerent states from three-fourths to four-fifths of all industry was by the time of the armistice converted to the meeting of war requirements, direct or indirect.

I. GREAT BRITAIN

The system of state control of trade and industry in Great Britain, which played so vital a part in the successful issue of the war, was not planned as a comprehensive whole by anything in the nature of an economic general staff, but was built up gradually in a number of different departments as a series of partial adjustments to particular needs and emergencies. In many ways it was characteristic of British temperament. Modern Germany had shown a capacity for large-scale organization of trade and industry which was foreign to the British tradition. Great Britain was, and still is, the home of an obstinate individualism and independence of character which resisted bureaucratic regulation and made even co-operation in trade and industry difficult. France too had a traditional way of thinking based on first principles and clear-cut definition of rights and duties which was equally alien to British psychology. The Englishman distrusted logic and definitions, and prided himself on being able to "muddle through." His system of government was based on an unwritten constitution, a genius for compromise and a profound distrust of State interference.

With such a background State control of trade and industry on the scale it eventually reached would have been unthinkable before the war and certainly formed no part of the Government's plan of operations in the event of a European war. The only measure of State intervention which had been carefully worked out

before the war was the taking over of the railways. This was carried out in August, 1914, and throughout the war the railways of the country were run by a Railway Executive on behalf of and for the account of the State. The British "War Book" contained no other plans for State intervention in trade and industry.

Throughout the war there were two slogans which must have been repeated many hundreds of times, in scores of different contexts—"Every private interest must be subordinated to the successful prosecution of the war" and "There must be as little interference as possible with the normal channels of trade." The real problem was to determine the exact degree of interference with normal trade channels which was necessary for the successful prosecution of the war. On this question opinions varied widely at different times and among different persons. In the abstract there was an almost universal bias against State interference. Manufacturers and traders naturally believed in freedom of trade, the rights of property, and the merits of *laissez-faire*; they had a deep-rooted dislike for the restrictions on individual liberty and private enterprise which State Socialism implied. By a process of rationalisation this instinctive antipathy gave rise to the axiom that State management was necessarily inefficient and that Government interference would therefore only make matters worse. If this were true, it followed that to substitute an inefficient for an efficient system of industrial organisation just when the nation was fighting for its existence, would be suicidal folly. Nor was the attitude of ministers and departmental officials very different. They distrusted the power of the Government to intervene successfully in matters on which there was no past experience to serve as a guide.

During the early stages of the war "business as usual" was the accepted doctrine. During the first few months the main problem was to combat unemployment and get the wheels of industry re-started in the normal channels, or, if that was impossible owing to the blockade of Central Europe, to open new markets in other parts of the world. In the absence of any plan of industrial mobilization for war, this was the only possible policy to pursue. A prosperous state of trade, regular employment at good wages and high profits for the revenue to tax and the Treasury to borrow, were regarded with good reason as essential conditions for the successful prosecution of the war.

First Steps in State Control.—Three large measures of State intervention, however, were introduced in the first month of the war, the first of which—the taking over of the railways—has already been mentioned. The second was in the sphere of finance. The Government suspended the Bank Act, introduced a State paper currency and placed the credit of the nation behind approved commercial bills payable by enemy and other debtors, who were unable to meet their liabilities. These two measures saved the money market from an acute crisis; but at the same time opened the door for that expansion of currency and bank credit under Government auspices, which more than anything else was responsible for the rise of prices throughout the war. So far as State control was designed to combat high prices, it was an indirect consequence of the system of inflation by which the war was to a considerable extent financed. As Lord Rhondda said in Nov. 1917 (Parl. Debates, House of Lords, vol. XXVI., cd. 1077, 1917):—"The real controller of prices is not the Food Controller but the Treasury. The principal factor in the rise of prices is the expansion of currency arising from inflation of credit and the issue of large amounts of paper money." Lastly the Government set up the Royal Commission on Sugar Supply to monopolise the purchase and import of sugar on Government account. The outbreak of war cut off all supplies from Central Europe, which in 1913 sent over 75% of the sugar imported into Great Britain. Large purchases were made by the Government in other markets within the first three weeks of the war, and from that time onwards the import and distribution of sugar was carried on under direct State control. (See FOOD, MINISTRY OF.)

The next steps in control arose as a result of the difficulties experienced in obtaining military supplies for the British and Allied armies. In July 1914 the Army Contracts Department of the War Office consisted of 56 officials and clerks. A staff of not more

than 20 was sufficient to handle the business of purchasing munitions and explosives under the system of competitive tendering then in vogue. (In Nov. 1913, the staff employed by the Ministry of Munitions for the administration of complete control numbered 65,142.) By Oct. 1914, the centralised buying machinery of the War Office, which had functioned smoothly and efficiently before the war, as a result of reforms introduced after the Crimean and South African wars, was becoming paralysed. In Nov. 1914, the new director of army contracts, U. F. Wintour C.B., C.M.G., presented a report to the army council which contained the following sentences, the truth of which was not generally realised for many months: "The war is a war of organisation, in which the raising of men is one very important item. It is equally important that they should be equipped, clothed, fed and provided with guns, arms and ammunition. For the provision of these necessities, industry, and industry alone, has to be relied upon, and the rapidity and effectiveness with which industry can be organised to meet the emergency cannot but have an enormous influence upon the issue of the struggle." A proposal was made in Oct. 1914, that the Government should take over the big armament firms as they had already taken over the railways, but the authorities at that time shrank from assuming such a responsibility and preferred to rely on private enterprise and the law of supply and demand to produce an adequate flow of munitions. In June 1915, with the establishment of the Ministry of Munitions, the theory that industry could be left to adapt itself of its own accord to war needs was abandoned. National organisation and detailed control of supplies, prices and methods of production were introduced. National factories were built; raw materials of all kinds required for making munitions were imported on Government account and distributed at fixed prices; and manufacturers, instead of being left to produce munitions or not as they thought fit at prices determined by their own sense of propriety, were now compelled to produce them at prices based on cost and if necessary were instructed how to do it. (See MUNITIONS, MINISTRY OF.)

The Path to General Control.—By requisitioning practically the whole output of the engineering industry and making use of nearly all the iron and steel obtainable for making munitions, the Ministry of Munitions virtually suppressed private trade and ignored civilian needs. The Army Contracts Department of the War Office on the other hand, which continued to purchase food, textiles, leather goods and other miscellaneous articles for the Army, only needed a proportion, though a growing proportion, of the national supplies. Civilian requirements had to be met, and this introduced a competing demand which had somehow to be reconciled with military necessities. It was this that led eventually to the extension of State control to cover the supply and distribution of many of the necessities of life for the whole population.

During the first period, which may roughly be defined as the first twelve months of the war, the problem was primarily that of obtaining supplies for the forces regardless of price. This in itself was by no means a simple problem. It soon became evident that supplies were lacking, first, because only those familiar with Army requirements were invited to tender, or if invited were able or willing to do so; secondly, because manufacturers were either full up with private orders, or, with large private orders on their books, were unable to offer their whole output; and thirdly, because in certain items the requirements outran the productive capacity of the industry to meet them. In nearly every case delays inherent in the purchasing machinery of the War Office aggravated the difficulties; and the confusion and dislocation caused by speculation, by competitive buying on the part of local commands and Allied delegates and by uncertainties about supplies of raw material, the need of the Army for men and the probable requirements of the War Office, rendered some more systematic form of organisation essential, if the Government was to count on being able to obtain what it wanted. This stage was marked by negotiations with representative associations or committees able to speak on behalf of a whole industry, and the substitution of collective agreements covering a long period and a wide area of production for the previous system of piece-meal demands, indi-

vidual tenders, and frenzied speculation.

The next stage in the problem was marked by the growing importance attached to the question of price. Hitherto with minor exceptions the prices paid by the Government had been those that any large buyer would have had to pay; they were determined by market forces and on the whole were neither more nor less than private individuals had to pay for similar goods. As a result, however, of Parliamentary criticism of Government extravagance, but without any express sanction from Parliament (which at that time was even more opposed to measures of State interference than the Government itself), attempts were made by voluntary agreement to base prices on cost of production and a reasonable profit. Later this principle, known as the "costings system," was embodied in regulations 7 and 2b of the Defence of the Realm Regulations, and it became the accepted doctrine that Government Departments had not merely the right, but the duty, to purchase supplies at prices bearing no necessary relation to market prices. The culminating point came when the right to fix maximum prices was laid down first by an administrative extension of the right to licence dealings, and finally by explicit mention in regulations 2b and 2f. Thus the price problem was solved in theory and in law (at least for the duration of the war) by giving the Government the power to fix its own prices. Before the end of the second year of the war this right had been successfully established, having been applied by the Ministry of Munitions to certain metals as early as Sept. 1915 and by the War Office to the whole of the domestic wool clip in June 1916.

During the second year the twin problem of supplies and prices began to develop more general implications and to cover an ever-widening range of commodities and processes. The corollary of limited State interference with market forces was more State interference; control and centralized purchase had to be extended from the finished article to the raw material. This introduced further problems. The Government had to devise the best methods, varying greatly in different trades, for buying raw materials in foreign markets or for controlling their purchase by traders. The control of purchase, import and shipment of raw materials was adopted by the War Office in March 1916, for Russian flax, in May 1916 for kips, and in August 1916 for jute. In the meantime the decision to requisition the domestic wool clip in June 1916 raised a new set of problems relating to the treatment of the farmer and the purchase of agricultural produce at fixed prices from hundreds of thousands of individual growers. The State had now to become wholesale collecting merchant as well as wholesale distributing merchant.

Control of Materials, Industry and Man-power, 1917.—In the third year of the war a change of Government occurred, which reflected and emphasized the growing changes that were taking place in the economic situation. The shortage first of finance, and then of tonnage, became increasingly stringent towards the end of 1916 and the beginning of 1917, and signs of actual shortage were becoming pronounced in certain essential raw materials. All three reasons added weight to the general considerations which by that time were beginning to favour control of raw materials. The War Office accordingly carried through negotiations for the purchase of the whole of the Australian and New Zealand wool clips. The vast scale of the Government's operations in the woollen and worsted industry now brought to the fore two problems which had not hitherto needed any special attention: the maintenance of the export trade and the provision of necessary supplies for the civilian population. The first was of importance owing to the difficulties of the financial situation and the need of obtaining foreign currency to pay for essential imports. But after the United States had joined the Allies foreign exchange difficulties ceased to be so pressing a problem, and the shortage of tonnage and the need for conserving raw materials for military and essential civilian needs, rendered the maintenance of the export trade of secondary importance in the system of war economy. The provision of supplies for the civilian population, however, rapidly became from Jan., 1917, onwards one of the most difficult and complex problems of the whole war organization, and it was in the establishment of the Ministry of Food and the introduction of standard clothing and

6. Railway Executive 7. Port and Transit Executive 8. Canal Control Committee 9. Liquor Traffic Control Board 10. War Trade Department (Import & Export Regulations) 11. Food Production Department 12. Director General of National Service	These war organizations, with the exception of the Food Production Department, were connected with the Board of Trade, though they necessarily had relations with other departments. The Food Production Department was attached to the Ministry of Agriculture.			

boot schemes, with the object of supplying the necessities of life for civilians and ensuring their fair distribution at controlled prices, that Government control during the war approached nearest to the programme of State Socialism. (*See FOOD, MINISTRY OF.*) The year 1917 also marked the most critical point in the man-power problem. A director-general of national service was appointed to facilitate the release of men for the Army, to restrict employment in non-essential trades and industries, and to secure the transfer of labour where it was most required. Finally, towards the end of 1917, the necessity of rendering greater assistance to the Allies both in tonnage and supplies led to the imposition of further restrictions on civilian consumption, to the establishment of a common programme of imports for all the Allies, and to the gradual recognition of the principle of equality of sacrifice and the pooling of resources. (*See ALLIED MARITIME TRANSPORT COUNCIL.*)

Control by 1918.—By the middle of 1918 the national organization of war control had reached approximately its final stage. There was virtually no trade or industry which was not subject to control in some form or other. The Ministry of Munitions and the Ministry of Food between them controlled 70 per cent. of the country's imported supplies and followed up control of import by control of price, distribution and manufacture. The Ministry of Munitions covered the iron and steel industry, the non-ferrous metals industry, explosives and chemicals, machinery, mineral oils, glass manufacture and mechanical transport. The Ministry of Food through the Wheat commission, the Sugar commission and its supply departments was responsible for importing and distributing cereals, sugar, meat, dairy produce, vegetable oils, fish, fruit, tea and coffee and controlled the price and distribution of most home-produced foodstuffs. The Raw Materials department of the War Office controlled the woollen and worsted industry, the leather industry, boot and shoe manufacture, and the flax, hemp and jute industries. Under the Board of Trade were ranged the Coal Controller, the Railway Executive, the Port and Transit Executive Committee, the Canal Control Committee, the Cotton Control Board and the import of paper and pulp. The Ministry of Shipping controlled shipbuilding, the shipping industry and the allocation of tonnage, and through its programme committees and the Allied Maritime Transport Council acted as a co-ordinating body for all importing departments. The War Trade Department issued import and export licenses on the advice of the appropriate Departments for such foreign trade as still remained in private hands. The Liquor Traffic Control Board, the Food Production Department and the Director General of National Service dealt with the remaining field of home production—the last-named by restricting employment in non-essential industries. Even such industries as piano-making came under war control and found themselves precluded from obtaining the labour and material they required. One of the last conferences on control held at the Board of Trade in Oct. 1918, was to decide whether the responsibility for controlling the manufacture, price and distribution of candles

should be entrusted to the Tobacco and Matches Control Board or to the Oils and Fats Department of the Ministry of Food, which was already controlling soap.

A glance at the accompanying chart illustrates the immense field over which control was exercised and the large number of departments concerned in its administration. The principle of piecemeal growth rather than logical planning favoured initiative and elasticity, but raised problems of overlapping and lack of co-ordination which had to be met by inter-departmental conferences and in the last resort by the intervention of the Cabinet. To deal with questions of priority in supply of labour and materials the Cabinet appointed in 1917 a War Priorities Committee, which in 1918 had as many as seventeen sub-committees.

The system of national organization thus built up rested in the last resort on the quite simple consideration that to the extent to which labour and capital were not engaged in essential war services, the nation's war effort was being weakened. In other words the political economy of war consists in the economical direction of the nation's resources towards the greatest possible efficiency in war. This involves (1) economy of man-power, to release men for the army and supply labour for essential services; (2) economy of finance, to prevent wasteful private expenditure and enable the nation to purchase supplies from abroad; (3) economy of transport, or the avoidance of all unessential movement of goods and the reduction of land and sea transport to the minimum necessary; (4) economy of production, or the centralized planning of productive activity in the right order of priority to meet essential requirements and with the minimum of waste and duplication of effort; and (5) economy of consumption, or the rationing and limitation of current consumption of food and necessities, with the prohibition of the manufacture and sale of luxury articles.

The above principles were never of course completely realized in practice, but they all nevertheless influenced the policy in some sphere or other in varying degrees and with varying success. Their literal application on a universal scale would have been politically and psychologically impossible. War control appears to violate human instincts and human traditions even more than the institution of war itself; and the military effort of a nation at war is seen to depend not merely on the strength of its armed forces but on the extent to which the civilian population will submit to irksome restrictions and interference in the normal routine of everyday life. (E. M. H. L.)

The Future of Control.—The essence of war control of trade and industry is the replacement of private enterprise by collective organization. Control is clearly necessary in war time; but inasmuch as the conditions of war are wholly unlike those of peace, it is said that the experience of State control during the war gives us no guidance on the vexed question of the degree of State intervention which may be desirable in peace. This statement has a large measure of truth, but the question merits some further examination.

In the first place it is evident that if the League of Nations

breaks down and the Great Powers were to engage in another world war. State control on a drastic and comprehensive scale would be introduced in each country. The organization would probably start about where it left off in the last war; and if the world's economic resources proved able to stand the strain of a prolonged struggle, the final stage would be a sort of military communism compared with which the existing system in Russia would appear a very paradise of liberty. Private property would cease to exist; freedom of speech, freedom of thought and freedom of movement would be abolished; the whole population would be conscripted and not only their food but their incomes would be rationed down to the minimum necessary to support life. The public and private resources of the community would be wholly devoted to the prosecution of the war and the privileges and amenities now enjoyed by the few would be wiped out in the interests of social harmony. Personal freedom and private property are condemned by the exigencies of modern war. This is an aspect of the matter which has received too little attention and provides, perhaps, an additional reason for taking risks, and even making sacrifices, in the cause of peace, disarmament and the abolition of war.

But setting aside the possibility of another war, the experience of war control is held by some to have other lessons that may be applied in peace. Short of rationing, it is said, and the more extreme forms of arbitrary interference with personal freedom and private enterprise, there are still left many features of war organization which the State might well adopt in times of peace. Among these, for instance, might be the principle of State importation of primary foodstuffs and raw materials; the control of power and transport on national lines; the guarantee of fixed prices for certain staple agricultural products; and the compulsory amalgamation of competing firms into publicly supervised Cartels or Trusts. Such proposals would be included in the programme of some Socialist thinkers. At the other end of the scale would be the view of extreme individualists, who would not only oppose any extension of State control in peace but would maintain that the experience of State control during the war had demonstrated once more that State organization is necessarily inefficient and wasteful and in all circumstances inferior to private enterprise.

To those who preserve an open mind in this controversy or regard the question of the precise degree of State intervention or collective organization which is desirable in economic affairs as among the most important and difficult problems for the future to solve, two conclusions may suggest themselves: 1. that administration by public or semi-public bodies is not always and necessarily inefficient and inferior to private enterprise; 2. that collective organization of trade and industry is at its best where consumption or demand is fairly regular or can be foreseen with considerable accuracy. The field over which accurate measurement of future demand could be made during the war was enormously widened owing to the formulation of precise requirements by the military authorities and the limitations of tonnage. Nothing comparable to this stabilization of demand is conceivable in peace, except in a comparatively narrow field. In war "production for use" was possible because the "use" for which each product was required could be laid down with some confidence and the relative order of priority of different "uses" could be to some extent gauged. In peace, short of rationing or communism, production must be for a market, the essence of which is that it provides an automatic measure of the "usefulness" of products.

Even in the absence, however, of effective control over demand, it is still possible to regulate supply and thus indirectly influence consumption and prices. It is in this direction that post-war developments show a parallel to war control. Control of supply at source was the key which enabled the State in the interests of consumers to prevent prices rising. A similar technique can be applied to stabilize prices in the general interests of producers. In both cases the underlying principle is that within limits the play of economic forces can be modified and controlled by collective action. "Rationalization" of industry, "orderly" marketing, and "management" of credit can be regarded as lineal descendents of

ideas which had their origin or at any rate received a large stimulus from war control.

The underlying issue on which the study of war control may throw light, is not so much the question whether the State, conceived of as public Departments, should actually conduct this or that trade or industry; but how far the State, conceived of as the guardian and trustee of the general welfare, should permit or encourage, or itself initiate the sort of large-scale co-operation and collective planning which is now being tried out as an alternative to the unrestricted play of economic forces. *Laissez faire* and unregulated competition may be even more wasteful of wealth and welfare than the operation of trusts and monopolies. It is perhaps the task of State control to minimise the evils and preserve what is best in both systems.

II. GERMANY

The first systematic action toward industrial control was taken by Germany. Upon the declaration of war by England it became at once evident that overseas supplies of raw materials, on which German industry had become largely dependent, would be cut off. The conservation of supplies on hand and their appropriation to essential uses was imperative. Within a fortnight, at the instance of Walter Rathenau, the Government, in co-operation with the cartels, had completed a rapid survey of the material resources of the nation and had worked out a policy, based partly on the requisition of materials and plant, but mainly on voluntary agreements, which offered a reasonable assurance of the continuous supply of military necessities on the scale then contemplated as adequate—erroneously, as the development of the war proved. Through the Reichsbank and the system of financial institutions dependent on it the necessary credit was supplied without stint to all industrial enterprises regarded as essential for war. The mobilization plans provided from the outset for the exemption of "key-men," technical and administrative, and the suppression of unessential industries provided labourers to take the place of those who had been called to the colours. On Dec. 2, 1916, the control of industrial resources was strengthened by a law instituting an industrial conscription of labour, applying to all males between 16 and 60. Auxiliary measures stiffened Government control over industrial enterprises. But to the end of the war the essential basis of industrial control was the quasi-voluntary agreement between the Government and the independent business man or group of business men, with a reserve power of compulsion in the Government's hands resting on the control of materials, credit and labour. This power of compulsion served to secure supplies, but did not restrict prices so strictly as to preclude large war profits, with attendant manifestations of popular discontent that grew more serious as the war dragged on.

III. FRANCE

In France the outbreak of the war was followed by a mobilization of men for military service which took the experts and "key-men" out of industry along with those who could be easily replaced. In consequence economic life was seriously dislocated. Unemployment reached extraordinary proportions. After the mobilization in Aug. 1914, the principal industries employed on the average only 60% of their normal personnel, and as late as Jan. 1915, 20% of the industrial working population was unemployed.

French industry, being highly individualistic in spirit, was far slower than that of Germany to adjust itself to war needs and war control. Gradually, however, a machinery of control was set up, of which the most effective part was the disposition of manpower. Committees of economic action composed of business men and engineers were organised in the several departments, to co-operate with the military and administrative authorities in supplying labour to agriculture and the essential industries.

Price control, so far as the munitions and supplies for the army were concerned, was effected through contracts, with sufficient reserve power over labour, raw materials, transportation and credit on the side of the Government to ensure reasonable terms. The prices of products for the use of the civil population were

subject to an informal and inadequate control through the departmental committee of laymen co-operating with the administrative authorities. In neither case was the control rigid enough to check a rise in prices, which produced much discontent among the workers, whose wages did not rise in equal proportion.

IV. UNITED STATES

The situation in America, upon that country's entry into the War, was in many respects peculiar. The Allies had already attained to a practical maximum of their industrial war effort, and the demands of war were still rapidly expanding. In this effort American industry had already come to play a conspicuous part. Allied war industry was drawing heavily on America for steel, copper, cotton and a large class of wholly or partly finished war materials. A powerful chain of war industries had been built up in America; labour and materials were rapidly advancing in price, and profits rose on a huge scale.

The American Government had to meet the problem of supplying the American armies with the materials of war without cutting off the supplies needed by the Allies. Control was essential not only to national but to international ends. Whereas in the early part of the War each belligerent had aimed primarily at effecting the most practicable distributions of resources between its own military and essential civil uses, the United States from the outset was confronted with the problem of making the best practicable distribution among the military, Allied and essential civil uses. American control was bound to envisage the entire system of needs of the Allied and Associated Powers.

The difficulties to be overcome in instituting control were, however, all but insurmountable. No close relation between government and industry had been developed, as in Germany; neither was the American administrative system adapted to prompt co-ordination. At the outbreak of the War the army and navy, each enjoying the power of commandeering, were in a position to enter the market for supplies, in competition with the Allied purchasing agencies, and there was no authority anywhere competent to allocate limited supplies in the order of importance of needs or to keep prices within bounds. A council of national defence, consisting of the secretaries of War, the Navy, the Interior, Agriculture, Commerce and Labour, with an advisory council and a widely ramifying organisation of committees, of executives and experts, had been created prior to the declaration of war. Out of this grew a multiplicity of organs of control, a War Industries Board, a railway control, a control of ocean tonnage, a food administration, a fuel administration and a War Trade Board. But there was no central co-ordinating principle except the war powers of the President, which in the nature of the case could be exercised only sporadically.

Co-ordinated control of industry came into existence on March 4, 1918, when the President, by a letter, reorganised the War Industries Board and specified its duties, constituting it in effect the administrative organ with power to apply the President's war powers over industry. Mr. Bernard M. Baruch was named by the President chairman of the board, with direct responsibility for its functioning, the other members of the board to act in an advisory capacity.

As finally reorganised the board controlled the exercise of the power of requisitioning. The army and navy, the railroad administration, the food and the fuel administrations, the War Trade Board, the Shipping Board, the War Finance Corporation, the Allied Purchasing Commission and other agencies dealing with industry, were required under the President's orders to co-operate with the War Industries Board. Thus it became possible to secure effective co-ordination in the whole field of industry. The board was in a position to control exports and imports, the movement of traffic over the railways and coastwise shipping; it was able to ration out materials, fuel, power, credit facilities to every business establishment in the country, to place a check upon every construction enterprise, public or private, except on proof of absolute necessity, to standardise production in the interest of economy, and in short to do everything necessary to ensure that the resources of the nation at war should be applied most effectively

to the national needs, both of the people as a whole and of the military forces.

In America direct authority to fix prices was never granted by law nor established by executive order. The War Industries Board had, however, sufficient power to control prices in effect, and in case of need it actually controlled them. No specific theory of fair prices lay behind the board's control, but a conception of efficient economic organisation for war.

V. LABOUR AND PERMANENT ECONOMIC RESULTS

War control of industry in its highest phase of development amounted in effect to nationalisation of economic resources, labour, capital, material things. Men could not work at what they liked best or put their capital to the most lucrative uses or sell their materials and goods to the highest bidder. They were called on to subordinate their private interests to the national needs. The conception of public service became generalised, as it were, and although with the end of hostilities private motives were again given free play, the conception of service retained a large measure of its vitality, exerting a considerable influence upon action.

Labour, conceived of as "man-power," won recognition early in the history of war control as the most vital of the national resources. The proper provisioning of labour, care for the health of the labourer and his family, maintenance of proper housing standards and the like, assumed the rank of military necessities. Here too the influences set in motion in war carried over into times of peace.

One of the most striking results of war-time control was the revelation of the extent of economic waste in the conventional scheme of production. By co-ordination, by concentration of effort upon essentials and by curbing of excessive variety in forms through standardisation, it became possible for the United States, while maintaining 4,000,000 men under arms, to supply the civil needs of its population with no appreciable lowering of peacetime standards. While recognising that such extreme application to practical needs would in the long run be deadening to industry, most leaders of industry came out of the War convinced of the necessity of eliminating much waste that had gone unnoticed in the pre-War period.

War control of industry promptly fixed in the minds of those who participated in its decisions a conception of international economic interdependence. Control of the resources within a nation led straight to the necessity of controlling exports and imports, and this in turn led to an understanding of the need of permanent economic relations under which all nations might have equal access to the raw materials of the world. This remains a problem, the solution of which will tend to lessen war.

Another result of the war-time control was the more systematic survey of the potential resources, and their development where at all practicable. As a consequence, many resources are being developed in peace that formerly had been neglected. War control, with its compulsion to the use of substitutes, gave a greater freedom and elasticity to production, making a higher degree of efficiency possible in peace time. Incidentally to the control of industry, financial institutions, money and credit were everywhere subjected to control, with the result that new and more efficient methods of handling specie reserves and managing the flow of credit were devised and added to the peace times equipment.

Some countries, finding themselves cut off because of the War from their usual sources of manufactured articles, soon learned to make these things for themselves, with the result that when peace returned the old manufacturing countries found that a part of their former markets for manufactured articles had been permanently lost. And so with raw materials; new sources of supply and substitutes were found.

For the most part the achievements of war control were made possible only by the solidarity of feeling and concentration upon national purposes engendered by extreme national necessity. No conclusions as to national control in peace time can be deduced from them. But we have learned that government can co-operate with business to the advantage of both. What may be deduced

from the experience of the World War is that war under modern conditions demands drastic control of industry. War cannot now be conducted incidentally with business as usual. (B. M. B.)

BIBLIOGRAPHY.—There is no book adequately covering the whole field of War Control of Trade and Industry. Brief contemporary surveys are contained in the Reports of the War Cabinet for 1917 and 1918 (Cd. 9,005 and Cmd. 325). Different aspects of war control are dealt with in the volumes contained in the Economic and Social History of the World War (British Series), e.g., J. A. Salter, *Allied Shipping Control*; E. M. H. Lloyd, *Experiments in State Control*; H. D. Henderson, *Cotton Control Board*. The unpublished and official *History of the Ministry of Munitions* may be consulted at the London School of Economics and some other libraries. The following contain accounts of control based on first-hand information:—Sir Leo Chiozza Money, *The Triumph of Nationalisation*; Rt. Hon. C. Addison, *Politics from Within, 1911–1918* and *Practical Socialism*, vol. I.; F. H. Collier, *A State Trading Adventure*; and F. H. Hatch, *The Iron and Steel Industry, 1914–1918*; J. L. Garvin, *Economic Foundations of Peace* and A. C. Pigou, *Political Economy of War*. See also Bernard M. Baruch, *American Industry in the War* (Report of War Industries Board, 1921); Paul Willard Garrett, *Government Control over Prices, 1920*; Grosvenor B. Clarkson, *Industrial Am. in the World War, 1924*.

INE, West Saxon king, of the line of Ceawlin, succeeded Ceadwalla in 688. In the earlier part of his reign he was at war with Kent, but peace was made in 694, when the men of Kent gave compensation for the death of Mul, brother of Ceadwalla, whom they had burned in 687. In 710 Ine fought in alliance with his kinsman Nun against Gerent of West Wales and was victorious, and in 715 he repulsed an attempted invasion by Ceolred, king of Mercia. In 721 Ine slew the rebel Cynewulf, and in 722 his queen Aethelburg destroyed Taunton, which was held by Eadbricht, another rebel. In 725 Ine fought with the South Saxons, who had previously been subject to him, and slew their leader Aldbryht. In 726 he resigned the crown and went to Rome where he died shortly afterwards, being succeeded by Aethelheard in Wessex. Ine is said to have built the minster at Glastonbury. He issued a written code of laws for Wessex, which is still preserved.

See B. Thorpe, *Antient Laws*, i., 2–25 (1840); R. Schmid, *Gesetze der Angelsachsen* (1832, 2nd ed. 1858); *Anglo-Saxon Chronicle*, ed. J. Earle (1865); C. Plummer (1865); Bede, *Hist. Eccl.* ed. C. Plummer, iv., 15, v. 7 (1896); F. Liebermann, *Gesetze der Angelsachsen* (1898).

INEBOLI, a town on the north coast of Asia Minor, 70 m. W. of Sinub (Sinope). Ineboli represents the ancient *Abonoteichos*, famous as the birthplace of the false prophet Alexander, who established there (2nd century A.D.) an oracle of the snake-God Glycon-Asclepius. Alexander obtained leave from the emperor Marcus Aurelius to change the name of the town to *Ionopolis*, whence the modern name is derived. (See ALEXANDER THE PAPHLAGONIAN.) It is the first place of importance touched at by vessels going eastwards from Constantinople. The roadstead is exposed and landing difficult. The exports are chiefly wool and mohair. The population (1927) was 47,538.

INEBRIETY, LAW OF. The legal relations to which inebriety gives rise are partly civil and partly criminal.

I. Civil Capacity.—The law of England as to the civil capacity of the drunkard is practically identified with and has passed through substantially the same stages of development as the law in regard to the civil capacity of a person suffering from mental disease (see INSANITY). Unless (see III. *inf.*) a modification is effected in his condition by the fact that he has been brought under some form of legal control, a man may, in spite of intoxication, enter into a valid marriage or make a valid will, or bind himself by a contract, if he is sober enough to know what he is doing, and no improper advantage of his condition is taken (*cf. Matthews v. Baxter*, 1873, L.R. 8 Ex. 132; *Imperial Loan Co. v. Stone*, 1892, 1 Q.B. 599). The law is the same in Scotland and in Ireland; and the Sale of Goods Act, 1893 (which applies to whole of Great Britain), provides that where necessities are sold and delivered to a person who by reason of drunkenness is incompetent to contract, he must pay a reasonable price for them.

Under the Roman law, and under the Roman Dutch law as

applied in South Africa, drunkenness, like insanity, appears to vitiate absolutely a contract made by a person under its influence (*Molyneux v. Natal Land and Colonization Co.*, 1905, A.C. 555).

In the United States, as in England, intoxication does not vitiate contractual capacity unless it is of such a degree as to prevent the person labouring under it from understanding the nature of the transaction pending (see *infra*). The same rule is by implication adopted in the Indian Contract Act (Act ix. of 1872, s. 12). In some legal systems, however, habitual drunkenness is a ground for divorce or judicial separation (Sweden, Law of April 27, 1810; France, Code Civil, art. 231, *Hirt v. Hirt*, Dalloz, 1898, pt. ii., p. 4, and n. 4).

II. Criminal Responsibility.—Under the law of England, until early in the 19th century, voluntary drunkenness was never an excuse for criminal misconduct. Sir Matthew Hale (P.C. 32) took a fairly moderate view, viz., that a person under the influence of this voluntarily contracted madness "shall have the same judgment as if he were in his right senses." But the law on the subject was ultimately defined by the House of Lords in 1920, in the case of *Director of Public Prosecutions v. Beard* (1920, A.C. 479), in which all the earlier decisions were reviewed in the following terms: (1) Insanity, whether produced by drunkenness or otherwise, is a defence to the crime charged; (2) evidence of drunkenness which renders the accused incapable of forming the specific intent essential to constitute the crime should be taken into consideration with the other facts proved in order to determine whether or not he had this intent; (3) evidence of drunkenness falling short of a proved incapacity in the accused to form the intent necessary to constitute the crime, and merely establishing that his mind was affected by drink so that he more readily gave way to such violent passion, does not rebut the presumption that a man intends the natural consequences of his acts; (4) the test of criminal responsibility is not the same in the case of drunkenness as in the case of insanity, and upon a plea of drunkenness where insanity is not pleaded, the jury should not be asked to consider whether, if the accused knew what he was doing, he also knew that he was doing wrong.

The law of Scotland accepts, if it does not go beyond, later developments of that of England in regard to criminal responsibility in drunkenness. Indian law on the point is similar to English (Indian Penal Code, Act. xlv. of 1860, ss. 85, 86; Mayne, *Crim. Law of India*). See also the Criminal Code of Queensland (No. 9 of 1899), art. 28; the Penal Code of Ceylon (No. 2 of 1883), art. 79; the Criminal Code of Grenada (No. 2 of 1897), art. 51; and the Criminal Code of St. Lucia (1920, s. 22). Under the French Penal Code (art. 64), *il n'y a ni crime, ni délit, lorsque le prévenu était en état de démence au temps de l'action*. According to the balance of authority (Dalloz, *Rép.* tit., Peine, ss. 402 *et seq.*) intoxication is not assimilated to insanity within the meaning of this article, but it may be and is taken account of by juries as an extenuating circumstance (Ortolan, *Droit Pénal* i. s. 323; Chauveau et Hélie i. s. 360). Nor is it assimilated to insanity in Germany (Clunet, 1883, p. 311); but in Germany, as in France, intoxication may apparently be an extenuating circumstance. Under the Italian Penal Code (arts. 46–49) intoxication—unless voluntarily induced so as to afford an excuse for crime—may exclude or modify responsibility. In the United States the prevalent legal doctrine is similar to the English legal view.

There remains the question how far drunkenness itself is a crime. Mere private intoxication is not, in England, indictable as an offence at common law; but in all civilized countries public drunkenness is punishable when it amounts to a breach of the peace (see LIQUOR LAWS) or contravention of public order; and modern legislation in many countries provides for deprivation of personal liberty for long periods in case of a frequent repetition of the offence. Reference may be made in this connection to the Inebriates Acts, 1898, 1899 and 1900 (see III. *inf.*), and also to similar legislation in the British colonies and in foreign legal systems (e.g., Cape of Good Hope, No. 32 of 1896; Ceylon, Licensing Ordinance, 1891, ss. 23, 24, 29; New South Wales, Vagrants Punishment Act, 1866; Massachusetts, Acts of 1891, c. 427, 1893, cc. 474, 44; France, Law of Jan. 23, 1873, art. 6).

III. State Action in Regard to Inebriety.—This assumes a variety of forms. (a) Measures regulating the punishment of occasional or habitual drunkenness by fines or short terms of imprisonment. (b) Control in penal establishments for lengthened periods. (c) Laws prohibiting the sale of liquor to persons who are known inebriates: e.g., in England (Licensing Act, 1902); Ontario (Rev. Stats., 1897, c. 245, ss. 124, 125); New South Wales (Liquor Act, 1898, ss. 52, 53); Cape of Good Hope (No. 28 of 1883, s. 89). (d) Laws regulating the appointment of some person or persons to act as guardian or guardians, or who may be endowed with legal powers over the person and estate of an inebriate. Thus in France (Code Civil, arts. 489 *et seq.*) and Germany (Civil Code, art. 6 [3]), an inebriate may be judicially interdicted if he is squandering his property and thereby exposing his family to future destitution. (e) Control for the purpose of reformation. Legislation of this character provides reformatory treatment: (1) for the inebriate who makes a voluntary application for admission; (2) by compulsory seclusion for the inebriate who refuses consent to treatment and yet manages to keep out of the reach of the law; (3) for the inebriate who is a police court recidivist or who has committed crime caused or contributed to by drink. The legislation of Great Britain (Inebriates Acts, 1879–1900) deals both with voluntary application and with the commitment of criminal inebriates or of police court recidivists. A brief sketch of the English system must suffice.

The Inebriates Acts of 1879–1900 deal in the first place with non-criminal, and in the second place with criminal, habitual drunkards.

For the purposes of the acts the term “habitual drunkard” means “a person who, not being amenable to any jurisdiction in lunacy, is notwithstanding, by reason of habitual intemperate drinking of intoxicating liquor, at times dangerous to himself or herself, or incapable of managing himself or herself and his or her affairs,” although when sober no such danger or incapacity exists (*Eaton v. Best*, 1909, 1, K.B. 632). A person would become amenable to the lunacy jurisdiction not only when habitual drunkenness made him a “lunatic” in the legal sense of the term, but where it created such a state of disease and consequential “mental infirmity” as to bring his case within s. 116 of the Lunacy Act, 1890, the effect of which is explained in the article *INSANITY*. Any “habitual drunkard” within the above definition may obtain admission to a “licensed retreat” on a written application to the licensee, stating the time (the maximum period is two years) that he undertakes to remain in the retreat. When an habitual drunkard has once been committed to a retreat, he must remain in the retreat for the time that he has fixed in his application, subject to certain statutory provisions similar to those prescribed as to leave of absence and discharge from mental homes; and he may be retaken and brought back to the retreat under a justice’s warrant. The term of detention may be extended on its expiry, or an inebriate may be re-admitted on a fresh application, without any statutory declaration, and without the attesting justice being required to satisfy himself that the applicant is an habitual drunkard. Licensed retreats are subject to inspection by an inspector of retreats appointed by the home secretary, to whom he makes an annual report. There are also statutory provisions as to offences—(1) by licensees failing to comply with the requirements of the acts; (2) by persons ill-treating patients, or helping them to escape or unlawfully supplying them with intoxicating liquor; (3) by patients refusing to comply with the rules. The home secretary may (1) authorize the establishment of “State inebriate reformatories,” to be paid for out of moneys provided by parliament; and (2) sanction “certified inebriates’ reformatories” on the application of any borough or county council, or any person whatever, if satisfied concerning the reformatory and the persons proposing to maintain it.

Miscellaneous.—Any person convicted on indictment of an offence punishable with imprisonment or penal servitude (i.e., of any non-capital felony and of most misdemeanours), if the court is satisfied from the evidence that the offence was committed under the influence of drink, or that drink was a contributing cause of the offence, may, if he admits that he is, or is found by

the jury to be, an habitual drunkard, in addition to or in substitution for any other sentence, be ordered to be detained in a State or certified inebriate reformatory, the managers of which are willing to receive him. Again, any habitual drunkard who is found drunk in any public place, or who commits any other of a series of similar offences under various statutes, after having within 12 months been convicted at least three times of a similar offence, may, on conviction on indictment, or, if he consent, on summary conviction, be sent for detention in any certified inebriate reformatory. Habitual drunkenness has been held to be a ground for the refusal of restitution of conjugal rights (*Fisk v. Fisk*, 122 L.T. 803). Where the husband of a woman is an habitual drunkard, she may obtain a protection order; where the wife is an habitual drunkard, the husband may obtain an order equivalent to a decree for judicial separation (Licensing Act, 1902, s. 5). A convicted inebriate of 60 years or upwards may be disqualified for an old age pension (Old Age Pensions Act, 1908, s. 3). A parent who is convicted of an offence under the Children Act, 1908, may be sentenced to detention in a certified inebriate reformatory (s. 26).

BIBLIOGRAPHY.—As to the history of legislation on the subject see Parl. Paper No. 242 of 1872; 1893 C. 7008. See also Wyatt Paine, *Inebriate Reformatories and Retreats* (1899); Blackwell, *Inebriates Acts, 1879–1898* (1899); Wood Renton, *Lunacy* (1896). An excellent account of the systems in force in other countries for the treatment of inebriates will be found in Parl. Pap. (1902), cd. 1474.

(A. W. R.)

United States.—In the United States, by the decided weight of authority, the contract of a completely intoxicated person is voidable. It is capable of repudiation or ratification when the party becomes sober, and the ratification may be express or implied, the burden being upon him to take action within a reasonable period after he becomes sober to disaffirm it; otherwise ratification is presumed from his silence. The rule is the same in the United States as in England that a man may, in spite of intoxication, bind himself by contract, if he knows what he is doing and comprehends the consequences of his acts. If his intoxication utterly and entirely deprives him of his reason and understanding he may set his contract aside on the ground of drunkenness.

Voluntary intoxication carries with it the assumption by the drunkard of all criminal responsibility, while if the criminal act was committed when the intoxication was involuntary this is a complete defence to a criminal charge based on the act. However, the condition known as delirium tremens, when it has progressed to a degree establishing permanent insanity, which renders the person incapable of distinguishing between right and wrong, relieves him from criminal responsibility for his acts, even though the condition was voluntary in its inception. The theory and reason for the rule is that the man is insane, and his insanity is a defence even though it was produced by the voluntary excessive use of intoxicating liquors. (*People v. Rogers*, 18 N.Y. 9; *Flanigan v. The People*, 86 N.Y. 554; *State v. Haab*, 195 La. 230.) Intoxication, even though voluntary, may be adduced in evidence in those acts which become crimes when done knowingly or with a specific intent or purpose, and the courts have held that in such cases the fact of intoxication is admissible to negative the existence of such knowledge or intent, which is a necessary element of the crime.

The manufacture and sale of intoxicating liquors for beverage purposes in the United States is controlled by the 18th amendment to the Constitution, commonly known as the Volstead Act. This grew out of the so-called Prohibition Act of Nov. 21, 1918, upheld by the U.S. Supreme Court (*Hamilton v. Kentucky Distilleries, etc., Co.*, 251 U.S. 146; *United States v. Standard Brewery*, 251 U.S. 210; *Ruppert v. Caffey*, 251 U.S. 264), on the ground that the act was a proper exercise of the war powers granted to the United States by the Constitution. The National Prohibition Act (Oct. 28, 1919, chap. 83, Acts 66th Congress, 41 Stat. at L. 305) prohibits the manufacture, sale and transportation of intoxicating liquors for beverage purposes and the U.S. Supreme Court (*Ruppert v. Caffey*, *supra*) held that the provisions of the act extending such prohibition to malt liquors, whether intoxicating or not, with alcoholic content of $\frac{1}{2}$ of 1% of alcohol by volume, was a proper

exercise of the powers of Congress; thus the validity of the 18th amendment was upheld. The act itself made certain exceptions, under a permit system (chap. ii., ss. 12 and 13, and chap. iii., ss. 78 and 80), stating lawful uses of liquor; *i.e.*, for scientific, sacramental, medicinal and mechanical purposes. (See NATIONAL PROHIBITION ACT.) (J. P. EA.)

INFALLIBILITY, the fact or quality of not being liable to err or fail (Med. Lat. *infallibilitas*, *infallibilis*, formed from *fallor*, to make a mistake). At the present time the idea of infallibility in religious matters is most commonly associated with the claim of the Roman Catholic Church, and more especially of the pope personally as head of that Church, to possess the privilege of infallibility, and it is with the meaning and limits of this claim that the present article deals.¹ The substance of the claim to infallibility made by the Roman Catholic Church is that the Church and the pope cannot err when solemnly enunciating, as binding on all the faithful, a decision on a question of faith or morals. The infallibility of the Church, thus limited, is a natural outcome of the fundamental conception of the Catholic Church and its mission. Every society of men must have a supreme authority, whether individual or collective, empowered to give a final decision in the controversies which concern it. A community whose mission it is to teach religious truth, which involves on the part of its members the obligation of belief in this truth, must, if it is not to fail of its object, possess an authority capable of maintaining the faith in its purity, and consequently capable of keeping it free from and condemning errors. To perform this function without fear of error, this authority must be infallible in its own sphere. The Catholic Church has expressly claimed this infallibility for its formal dogmatic teaching.

The infallibility of the pope (*q.v.*) was first defined in 1870 at the Vatican Council. The exact formula for the papal infallibility is given by the Council in the following terms (Constit. *Pastor aeternus*, cap. iv.); "we teach and define as a divinely revealed dogma, that the Roman Pontiff, when he speaks *ex cathedra*—*i.e.*, when, in his character as Pastor and Doctor of all Christians, and in virtue of his supreme apostolic authority, he lays down that a certain doctrine concerning faith or morals is binding upon the universal Church—possesses, by the Divine assistance which was promised to him in the person of the blessed Saint Peter, that same infallibility with which the Divine Redeemer thought fit to endow His Church, to define its doctrine with regard to faith and morals; and, consequently, that these definitions of the Roman Pontiff are irreformable in themselves, and not in consequence of the consent of the Church." A few notes will suffice to elucidate this pronouncement.

(a) As the Council expressly says, the infallibility of the pope is not other than that of the Church; this is a point which is too often forgotten or misunderstood. The pope enjoys it in person, but solely *qua* head of the Church, and as the authorized organ of the ecclesiastical body united with him.

(b) The late date at which the dogma was defined is explained by the fact that the mode of exercising authority on the part of the Church has varied since the time of Christ; but it is affirmed that the dogma was already contained in that of the papal primacy established by Christ himself in the person of St. Peter. A certain dogmatic development is not denied, nor an evolution in the direction of a centralization in the hands of the pope of the exercise of his powers as primate; it is merely required that this evolution should be well understood and considered as legitimate.

(c) Infallibility is the guarantee against error, not in all matters, but only in the matter of dogma and morality; everything else is beyond its power, not only truths of another order, but even discipline and the ecclesiastical laws, government and administration, etc.

(d) Again, not all dogmatic teachings of the pope are under the guarantee of infallibility; neither his opinions as private instructor, nor his official allocutions, however authoritative they

¹On the idea of infallibility in reference to a written revelation, see INSPIRATION.

may be, are infallible; it is only his *ex cathedra* instruction which is guaranteed; this is admitted by everybody.

(e) The last phrase of the definition is aimed at Gallicanism and kindred doctrines, political rather than theological, which placed the authority of the Church above that of its head.

But when does the pope speak *ex cathedra*, and how is it to be distinguished when he is exercising his infallibility? As to this point there are two tendencies among Catholics. (i.) Some extend the privilege of infallibility to all official exercise of the supreme *magisterium*, and declare infallible, *e.g.*, the papal encyclicals. In this sense it was understood by Döllinger, who pointed out that the definition of the dogma would commit the Church to all past official utterances of the popes, *e.g.*, the Syllabus of 1864, and therefore to a war *à outrance* against modern civilization. This view was embodied in the circular note to the Powers, drawn up by Döllinger and issued by the Bavarian prime minister Prince Hohenlohe-Schillingsfürst on April 9, 1869. It was also the view universally taken by the German governments which supported the *Kulturkampf* in a greater or lesser degree. (ii.) Others, while recognizing the supreme authority of the papal *magisterium* in matters of doctrine, confine the infallibility to those cases alone in which the pope declares positively that he is imposing on all the faithful the obligation of belief in a certain definite proposition, under pain of heresy and exclusion from the Church (*cf.* J. Fessler, *Die wahre und die falsche Unfehlbarkeit der Päpste*; French trans. 1873). Those who hold this second view contend that it has never been officially condemned; and they are able, while admitting the supreme authority of the encyclicals, to assert that no infallible definition has been formulated by the popes since 1870.

The controversies occasioned by this question had started from the beginning of the Council, and were carried on with bitterness on both sides. The minority, among whom were prominent Cardinals Rauscher and Schwarzenberg, Hefele, bishop of Rotterdam (the historian of the councils), Cardinal Mathieu, Mgr. Dupanloup and Mgr. Maret, did not pretend to deny the papal infallibility; they pleaded the inopportune of the definition and brought forward difficulties mainly of an historical order. The majority, in which Cardinal Manning played a very active part, took their stand on theological reasons of the strictest kind; they invoked the *tu es Petrus* and the *pasce agnos* of Christ; they showed the popes, in the course of the ages, acting as the guardians and judges of the faith, arousing or welcoming dogmatic controversies and authoritatively settling them, exercising the supreme direction in the councils and sanctioning their decisions; they argued that the few historical difficulties did not involve any dogmatic defect in the teaching of the popes; they insisted upon the necessity of a supreme tribunal giving judgment in the name of the whole of the scattered Church; and finally, they considered that the definition had become opportune for the very reason that under the pretext of its inopportune the doctrine itself was being attacked.

The definition once proclaimed, controversies rapidly ceased; the bishops who were among the minority one after the other formulated their loyal adhesion to the Catholic dogma. The last to do so in Germany was Hefele, who published the decrees of April 10, 1871, thus breaking a long friendship with Döllinger. In France, though no bishops abandoned it, a few priests, such as Father Hyacinthe Loyson, refused their adhesion. The most distinguished among the German dissentients was Döllinger, who resisted all the advances of the archbishop of Munich, was excommunicated on April 17, 1871, and died unreconciled, though without joining any separate group. After him must be mentioned Friedrich of Munich, several professors of Bonn, and Reinkens of Breslau, who was the first bishop of the "Old Catholics" (*q.v.*).

"Infallibility" in the *Catholic Encyclopaedia*; and C. Mirbt, art. "Vatikanisches Konzil" in Herzog-Hauck, *Realencyklopädie* (full bibliography); "Infallibility" in Hastings' *Encyclopaedia of Religion and Ethics* (Protestant); H. E. Manning (cardinal), *Petri Privilegium*, 1871, and *The Vatican Decrees in their Bearing on Civil Allegiance*, 1875; J. H. Newman (cardinal), *Letter to the Duke of Norfolk*, 1875.

INFAMY, public disgrace or loss of character. Infamy occupied a prominent place in Roman law, and took the form of a censure on individuals pronounced by a competent authority in the State. Such a censure involved disqualification for certain rights both in public and in private law. In English law infamy as a cause of incompetency was abolished by 6 & 7 Vict. c. 85. The same has occurred in most of the codes which followed the Roman law in this relation, e.g., the Spanish penal code of 1848.

The word "infamous" is used in a particular sense in the English Medical Act of 1858, which provides that if any registered medical practitioner is judged by the General Medical Council, after due enquiry, to have been guilty of infamous conduct in any professional respect, his name may be erased from the medical register. The General Medical Council are the sole judges of whether a practitioner has been guilty of conduct infamous in a professional respect, and they act in a judicial capacity, but an accused person is allowed to appear by counsel.

See *Pratt v. British Medical Association*, 1919, 1 K.B. p. 270 and cited cases. As to dentists, see the Dentists Act, 1921, establishing a dental board.

INFANCY, in medical practice, the first year of life. On being born the normal infant cries lustily, drawing air into its lungs. As soon as the umbilical cord which unites the child to the mother has ceased to beat, it is tied about 2 in. from the child's navel and is divided above the ligature. The cord is wrapped in a sterilized gauze pad and the dressing is not removed until the seventh to the tenth day, when the umbilicus is healed.

The first event in a baby's life is its first bath. The room should be at a temperature of 70° F, and the bath water at 100° F. The child should be well supported in the bath by the left hand of the nurse, and care taken to avoid wetting the gauze pad covering the cord. In some cases infants are covered with a white substance termed "vernix caseosa," which may be carefully removed by a little olive oil. Sponges tend to harbour bacteria, so absorbent cotton wool should take their place. After the first ten days 94° F is the most suitable temperature for a bath. Night and morning, from the first, the mouth and nostrils should be cleansed with wet pledgets of cotton wool. When the baby has been well dried the skin may be dusted with pure starch powder to which a small quantity of boric acid has been added. The most important part of the toilet of a new-born infant is care of the eyes, which should be carefully cleansed with cotton wool dipped in warm water, and one drop of a 2% solution of nitrate of silver dropped into each eye. The clothes should consist exclusively of woollen undergarments, a soft flannel binder, which should be tied on, being placed next the skin, with a long-sleeved wool vest, and over this a loose garment of flannel coming below the feet and long enough to tuck up. Diapers should be made of soft absorbent material about 2 ft. square and folded in a three-cornered shape. An infant should always sleep in a bed or cot by itself. More than half the deaths from violence of children under one month are due to suffocation in bed with adults. A healthy infant should spend most of its time asleep, and should be laid into its cot immediately after feeding.

Physically, the first year is the most important one of the entire life cycle. Increase in height and weight and development of the organs of the body are greater than at any future similar period. The degree of health during the first year will determine, to a great extent, the health of the individual during later life. The main factor of proper infant care is nourishment, dependent upon the amount, character and regularity of feeding. Secondary factors of proper infant care are those which are concerned with the environmental conditions of life including fresh air, sunshine, sleep, cleanliness, bathing, exercise and the other measures of physical hygiene. The most definite evidence of health in infancy is an even continuous gain in weight in relation to height.

The normal infant at birth weighs about 7 lb. During the two or three days following birth a slight decrease in weight occurs, usually 5 to 6 oz. When nursing begins the child increases in weight up to the seventh day, when it will have regained its weight at birth. From the second to the fourth week after birth (according to Camerer) an infant should gain 1 oz. daily or 1½ to 2 lb.

monthly, from the fourth to the sixth month half to two-thirds of an ounce daily or 1 lb. monthly, from the sixth to the twelfth month ½ oz. daily or less than 1 lb. monthly. At the sixth month it should be twice the weight at birth. The average weight at the twelfth month is 20 to 21 lb. The increase of weight in artificially fed is less regular than in breast-fed babies.

Gain in weight is less in warm weather. Teething is apt to delay a regular gain in weight and from the seventh to the tenth month the weight may remain almost stationary or increase very little. The baby should be weighed once each week during the first six months and once every two weeks during the second six months. Weighing should take place at the same hour on the same day each week and with the same amount of clothing.

The average height at birth is about 19 in. If the weight of the baby is over or below seven lb., the height should be correspondingly greater or less. The important points in determining health are: first, the relation between height and weight and, second, the rate of increase in height and weight. From birth to three months, the increase in height will be about three in.; the same rate of increase should take place during the second three months and again during the following six months.

At birth, the circumference of the abdomen and of the chest should be the same; in the average baby, about 13½ in. The circumference of the head should be about 14 in. The chest and abdomen increase in size at the same rate and the head at a slightly less rate during the first year. At one year of age, the circumference of the head, chest and abdomen should be the same; about 18 in. for the average baby. Any disproportion to these measurements is evidence of malnutrition or some definite disease.

Food.—The ideal food for an infant is its mother's milk. Artificially-fed children are more liable to epidemic diseases. The child should be applied to the breast the first day to induce the flow of milk. The modern tendency is to feed it at 6 A.M., 10 A.M., 2 P.M., 6 P.M. and 10 P.M., thus the mother gets a night's rest. Frequently, however, these intervals have to be shortened.

Artificial Feeding.—The simplest artificial food is cow's milk, diluted with boiled water and with the addition of a little cream and milk sugar. At first two parts of water should be added to one of milk and week by week the water should be diminished until at three months equal parts of milk and water and at six months three times as much milk as water are used. A teaspoonful of cream and a quarter of a teaspoonful of sugar of milk in each feed are appropriate amounts. Unless the source is unimpeachable the milk should be either sterilized by boiling or pasteurized, i.e., subjected to a form of heating which, while destroying pathogenic bacteria, does not alter the taste. The milk in a suitable apparatus is subjected to a temperature of 65° C (149° F) for half an hour and is then rapidly cooled to 20° C (68° F).

Various patent foods are on the market, some of which are satisfactory, but great care must be exercised in their selection as many are injurious. All infants artificially fed should be given fresh orange juice daily, beginning with a teaspoonful at the end of the first month, gradually increasing the amount to two tablespoonfuls at the end of the fourth month and thereafter. Twice the amount of the juice of canned tomatoes (uncooked) and diluted with an equal amount of water may be used in place of the orange juice. These juices supply the needed vitamins which may be lacking in the pasteurized or boiled milk. (See VITAMINS; DIET.) As an additional aid to nutrition and to supply the vitamins that may be lacking in other foods, codliver oil may be given to babies more than one month old. The average dose is one-half teaspoonful at one month, one teaspoonful at two months, one and one-half teaspoonfuls at three months and two teaspoonfuls thereafter during the first year. This dose is given twice daily.

Additional foods may be given daily as follows: At four months, two tablespoonfuls of strained vegetable soup. At five months, three tablespoonfuls of the soup and one teaspoonful of vegetable pulp. At six months, one tablespoonful of strained cereal gruel, two ounces of vegetable soup and two teaspoonfuls vegetable pulp. At seven months, double the amount of cereal gruel and vegetable pulp, increase amount of vegetable soup by one ounce, add one-third slice dried bread. At eight months, give above amount cereal

gruel twice daily. At nine months, increase vegetable soup to four ounces and pulp to one tablespoonful, add one tablespoonful mixed codded egg. At 10 months, increase vegetable pulp to two tablespoonfuls, codded egg to two teaspoonfuls, dried bread to one-half slice, cook beef bone in soup stock. At 11 months, increase amounts of all foods, add one teaspoonful mealy part of baked potato and same amount strained applesauce.

Method of Modifying Milk.—Wash all utensils in hot soap suds and rinse in boiling water. Boil bottles, nipples and corks for three minutes. Measure sugar and dissolve in small amount of water; pour into pitcher and add full amount of water; stir milk in bottle and add amount for day's formula. Stir mixture and pour right amount in each feeding bottle. Cork the bottles and place them on ice. Keep at a temperature at or slightly below 50 degrees, Fahrenheit, until used. At feeding time replace cork with nipple, hold bottle in pan of hot water until contents are warm. Test warmth of milk by dropping a small amount on arm just above wrist; the milk should feel warm but not hot.

Rules for Feeding

1. Establish regular feeding habits and keep to them.
2. Feed by weight rather than age.
3. Wash bottles and nipples after each use; keep nipples in covered jar full of sterile water.
4. Give the baby water to drink from a bottle, cup or spoon between feedings.
5. Give the milk first at each feeding; then the additional foods.
6. Increase the additional foods gradually and in small amounts.
7. Decrease the amount of the milk formula at each feeding by the amount of other liquid given.
8. Give only one additional food at any one feeding.
9. Cook all cereals longer than the directions given on the package.
10. Strong and healthy babies can take solid food at an earlier age than weak and delicate babies can.
11. Vegetables used in making soup are: carrots, turnips, spinach, chard, celery, asparagus, lettuce, beet greens, onions, string beans, cabbage and cauliflower (not more than three at any one time); all vegetables should be fresh.
12. The formulae and other directions given for feeding apply to the average normal baby. If the baby is not gaining in weight or if any digestive disturbance develops, medical advice about the diet should be secured.

Normal Infant's Development.—A healthy infant should live out of doors during the daytime as much as possible, warmly clad, with a hot water bottle if necessary, protected from wind and rain and excessive sunlight. On the second day the eyes are sensitive to light, in the second month the infant notices colours, at the sixth month it knows its parents, and should be able to hold its head up. During the sixth month the baby usually begins to cut its temporary teeth. Attempts to stand are made about the tenth month, and walking begins about the fourteenth month. By this time the intelligence should be developed, memory is observed, and the child should be able to articulate a few small words. With the advent of walking and speech the period of infancy may be said to end.

Baker, *Healthy Babies* (Boston, 1920).

PHYSICAL HYGIENE

One of the most important questions in the physical hygiene of children is that of habit formation. Babies are born without habits. They acquire them and the type of habits formed depends upon the kind and regularity of infant care and the en-

vironment, or surroundings, of the baby and young child during these early, formative years of life. "Habit" may be defined as the repetition of an act until it becomes automatic and a more or less unconscious action.

The kind of habits we acquire affect health, development, mentality, character and adjustment to life. The majority of habits have their inception during the first five years of life and habit formation begins at birth. A common example of this occurs in earliest infancy. If a baby is taken up when he cries, he learns immediately that a cry will accomplish this desired result. If his cry does not bring this attention, he learns that it is useless to cry for this purpose and this type of crying habit is prevented. Habits of regularity in feeding, sleeping, bathing and the other functions of the body vitally affect health and the proper ones should be established as soon as the baby is born and persisted in without interruption.

While the best habit formation consists in the cultivation of good habits and the avoidance of bad habits, there are instances where the bad habits have already been formed and correction is necessary. For the prevention of bad habits which are concerned with the routine of daily life, it is essential to establish regular and fixed hours for feeding, sleep, bathing, exercise or play and bowel movements. For information regarding all except the last mentioned, see **NURSERY EQUIPMENT**. The more common bad habits which are to be prevented or corrected are: nail biting, sucking, the use of a pacifier, dirt eating, bed wetting and masturbation.

Training for Regular Bowel Movements.—This may be started during the second month. Set a small chamber between the nurse's knees, place the baby on this with his body supported firmly and his back braced against the nurse's chest. At first it may be necessary to insert into the opening of the rectum, the end of a rolled cone of oiled paper or the end of a piece of white soap whittled into the shape and size of a lead pencil. As it is normal for the baby to have one or two bowel movements a day, this practice should be carried out twice daily; immediately after the first morning and the late afternoon feedings. It is probable that for the first week or two the effort will be unsuccessful but after that time the use of the cone or soap may be omitted, the baby will begin to learn what is expected and the habit of regular bowel movements at these times should be established. Persistence and absolute regularity are essential for success.

Sucking and Nail Biting.—The habit of sucking a piece of the clothing, a corner of the blanket, the thumb or the fingers begins early in infancy. This may be a sign of hunger and attention should be paid to the amount and the quality of the feeding. If uncorrected, this habit may persist until the child is five or six years old. The results of this practice may be serious and lead to misshapen lips, irregular teeth, malocclusion of the jaws, deformed palate and excessive adenoid growths. The flow of saliva is stimulated and digestive disturbances may result. The use of a pacifier is equally harmful and will produce the same symptoms and deformities. In addition it may cause an infection of the mouth or a general infectious disease as it is practically impossible to keep a pacifier clean. Nail biting commonly begins later in life—at about three years—and is most common in nervous children and those who are undernourished. The prevention and treatment of these conditions consists of attention to the diet and general health of the child, avoidance of the use of the pacifier and, the emotional development of the child permitting, some form of mechanical restraint.

Bed Wetting.—Children should be able to control the bladder at two years of age. If lack of control persists beyond this time, either during the day or night, some physical cause for this condition may be looked for. This may be excessive nervousness, anemia, malnutrition, local irritation in the genital region or a rectal irritation due to worms. Such causes should be sought for and removed by competent medical care. Early training in good habits of bladder control may be commenced by the end of the first year and consist in placing the child on the chamber at regular intervals during the daytime, the last thing before bedtime and once during the night. If the bed wetting persists, the child should sleep without a pillow and the foot of the bed may

be raised slightly. All fluids in the diet should be eliminated after four o'clock in the afternoon. At the same time a definite effort should be made to interest the child in overcoming the habit. An appeal to his self-respect, pointing out the way in which he differs from other children in this practice and the promise of recognition of his self-helping efforts by simple rewards have been found helpful.

Masturbation.—As this habit is more often an emotional than a physical one, proper attention to the mental hygiene of early childhood insures the best results. It must be remembered however that irritation of the genital region may produce efforts at masturbation and a physical examination and medical advice are essential in such instances. In the majority of instances the action is reflex and mainly subconscious with no moral significance.

Intelligent guidance and simple rewards yield the best results in correcting all types of bad habits. Punishment will invariably bring harmful consequences. (S. J. B.)

INFANT, in non-legal use, a very young child, a baby, or one of an age suitable to be taught in an "infant school"; in law, a person under full age, and therefore subject to disabilities not affecting persons who have attained full age.

This article deals with "infants" in the last sense; for the more general sense see *INFANCY* and *CHILD*. The period of full age varies widely in different systems, as do also the disabilities attaching to nonage (non-age). In Roman law, the age of puberty, fixed at 14 for males and 12 for females, was recognized as a dividing line. Under that age a child was under the guardianship of a tutor, but several degrees of infancy were recognized. The first was absolute infancy; after that, until the age of seven, a child was *infantiae proximus*, and from the eighth year to puberty he was *pubertati proximus*.

By the law of England full age is 21, and all minors alike are subject to incapacities. The period of 21 years is regarded as complete at the beginning of the day before the birthday; for example, an infant born on the first day of January attains his majority at the first moment of the 31st of December. The incapacity of an infant is designed for his own protection, and its general effect is to prevent him from binding himself absolutely by obligations. Of the contracts of an infant which are binding *ab initio*, the most important are those relating to "necessaries." By the Sale of Goods Act, 1893, an infant liable on a contract for necessities can be sued only for a reasonable price, not necessarily the price he agreed to pay. The same statute declares "necessaries" to mean "goods suitable to the condition in life of the infant, and to his actual requirements at the time of the sale and delivery." In the case of goods having a market price, the market price is reasonable. In all other cases the question is one of fact for the jury. The protection of infants extends sometimes to transactions completed after full age; the relief of heirs who have been induced to barter away their expectations is an example. "Catching bargains," as they are called, throw on the persons claiming the benefit of them the burden of proving their substantial righteousness.

At common law a bargain made by an infant might be ratified by him after full age, and would then become binding. Lord Tenterden's act required the ratification to be in writing. But now, by the Infants' Relief Act, 1874, "all contracts entered into by infants for the repayment of money lent or to be lent, or for goods supplied or to be supplied (other than contracts for necessities), and all accounts stated, shall be absolutely void," and "no action shall be brought whereby to charge any person upon any promise made after full age to pay any debt contracted during infancy, or upon any ratification made after full age of any promise or contract made during infancy, whether there shall or shall not be any new consideration for such promise or ratification after full age." For some years after the passage of this statute highly conflicting views were held as to the meaning of the part of sec. 2 whereby it was enacted that "no action shall be brought, whereby to charge any person . . . upon any ratification made after full age of any promise or contract made during infancy." Some authorities were of opinion that the section

only applied to the three classes of contract made void by the previous section, viz., for goods supplied, money lent and on account stated. Others thought the effect to be that no contract, except for necessities, made during infancy could be enforced after the infant came to full age. After several conflicting decisions it has been settled that both these views were wrong. Of the infant's contracts voidable at common law there were two kinds. The first kind became void at full age, unless expressly ratified. The second kind were valid, unless repudiated within a reasonable time after full age was attained by the infant. The Infants' Relief Act (sec. 2) strikes only at the first class and leaves the second untouched. Thus a promise of marriage made during infancy cannot be ratified so as to become actionable; but an infant's marriage settlement, being of the second class, is valid, unless it is repudiated within a reasonable time after the infant attains full age. What is a reasonable time depends on all the circumstances of the case. In a case decided in 1893 a settlement made by a female infant was allowed to be repudiated 30 years after she attained full age, but the circumstances were exceptional. A contract of marriage may be lawfully made by infants; since the passing of the Age of Marriage Act, 1929, marriageable age is 16 for both sexes. So an infant may bind himself by contract of apprenticeship or service. Since the passing of the Wills Act, an infant, except he be a soldier in actual military service or a seaman at sea, is unable to make a will. Infancy is in general a disqualification for public offices and professions, e.g., to be a member of parliament or an elector, a mayor or Burgess, a priest or deacon, a barrister or solicitor, etc.

Before 1836 the custody of an infant belonged in the first place, and against all other persons, to the father, who was said to be "the guardian of his children by nature and nurture"; and the father might by deed or will dispose of the custody or tuition of his children until the age of 21.

The Guardianship of Infants Acts.—The Guardianship of Infants Act, 1886, placed the mother almost on the same footing as the father as to guardianship of infants. On the death of the father the mother becomes guardian under the statute, either alone when no guardian has been appointed by the father, or jointly with any guardian appointed by him under 12 Chas. II. c. 24. A change of the law even more important is that whereby the mother may by deed or will appoint a guardian or guardians of her infant children to act after her death. If the father survives the mother, the mother's guardian can only act if it be shown to the satisfaction of the court that the father is unfitted to be the sole guardian. On the death of the father, the guardian so appointed by the mother acts jointly with any guardian appointed by the father. The act of 1886 also gives power to the high court and to county courts to make orders, upon the application of the mother, regarding the custody of an infant, and the right of access thereto of either parent. The court must take into consideration "the welfare of the infant, and . . . the conduct of the parents, and . . . the wishes as well of the mother as of the father." The same statute also empowers the high court of justice, "on being satisfied that it is for the welfare of the infant," to "remove from his office any testamentary guardian or any guardian appointed or acting by virtue of this act," and also to appoint another in place of the guardian so removed. Power is given to a court sitting in divorce practically to take away from a parent guilty of a matrimonial offence all rights of guardianship.

The passing of the Guardianship of Infants Act, 1925, has brought about a further very important change in the law on this subject and this act is to be "construed as one with" the act of 1886. The welfare of the infant is declared to be "the first and paramount consideration" in the making of a custody order, but the principle of equality between the sexes is "now to obtain with respect to the guardianship of infants," so that "the mother shall have the like powers to apply to the court" as are possessed by the father. It is, however, in the extension of jurisdiction to courts of summary jurisdiction that the act is most remarkable, since it confers upon these courts powers differing very widely from those which formed the original basis of their jurisdiction.

This extension is of immense benefit to the very poor, amongst whom quarrels as to the custody of children are not less common than amongst those able to afford more expensive litigation. The incorporation of the act of 1886 with the act of 1925 has given rise to a curious difficulty. The former act gave the mother the right to apply, but did not mention the father; but as right of application to a court of summary jurisdiction is purely statutory, it would appear that the father had no right to apply to such a court. Sec. 16 of the Administration of Justice Act (1923), however, has explicitly conferred the right of application on the father.

Another radical change has been made in the rights of parents as to guardianship of their children. In consequence of several cases where, after children had been rescued by philanthropic persons from squalid homes and improper surroundings, the courts had felt bound by law to redeliver them to their parents, the Custody of Children Act, 1891, was passed. A parent who has abandoned or deserted his child, is, *prima facie*, unfit to have the custody of the child. And before the court can make an order giving him the custody, the onus lies on him to prove that he is fit. The same rule applies where the child has been allowed by the parent, "to be brought up by another person at that person's expense, or by the guardians of the poor-law union, for such a length of time and under such circumstances as to satisfy the court that the parent was unmindful of his parental duties." Many cases of this kind can now be dealt with most satisfactorily under the Adoption of Children Act, 1926, which has decreased to a large extent the importance of the earlier legislation. (*See ADOPTION.*)

In the same direction as the Custody of Children Act, 1891, and the Guardianship of Infants Act, 1925, is the Children Act, 1908, whereby considerable powers have been conferred on courts of summary jurisdiction. (*See CHILDREN, PROTECTIVE LAWS.*)

There is not at common law any corresponding obligation on the part of either parent to maintain or educate the children. The legal duties of parents in this respect are those created by the poor laws, the Education Acts and the Children Act, 1908.

An infant is liable to a civil action for torts and wrongful acts committed by him. But, as it is possible so to shape the pleadings as to make what is in substance a right arising out of contract take the form of a right arising from civil injury, care is taken that an infant in such a case shall not be held liable. With respect to crime, mere infancy is not a defence, but a child under seven years of age is presumed to be incapable of committing a crime, and between seven and 14 his capacity requires to be affirmatively proved. After 14 an infant is *doli capax*.

Scotland.—The law of Scotland follows the leading principles of the Roman law. The period of minority (which ends at 21) is divided into two stages, that of absolute incapacity (until the age of 14 in males, and 12 in females), during which the minor is in pupilarity, and that of partial incapacity (between 14 and 21), during which he is under curators. The guardians (or tutors), of the pupil are either tutors-nominate (appointed by the father in his will); tutors-at-law (being the next male agnate of 25 years of age), in default of tutors-nominate; or tutors-dative, appointed by royal warrant in default of the other two. No act done by the pupil, or action raised in his name, has any effect without the interposition of a guardian. After 14, all acts done by a minor having curators are void without their concurrence. Every deed in nonage, whether during pupilarity or minority, and whether authorized or not by tutors or curators, is liable to reduction on proof of "lesion," *i.e.*, of material injury, due to the fact of nonage, either through the weakness of the minor himself or the imprudence or negligence of his curators. Damage in fact arising on a contract in itself just and reasonable would not be lesion entitling to restitution. Deeds in nonage, other than those which are absolutely null *ab initio*, must be challenged within the *quadriennium utile*, or four years after majority.

The Guardianship of Infants Act, 1886, the Custody of Children Act, 1891, the Children Act, 1908, and the Guardianship of Infants Act, 1925, mentioned above, all apply to Scotland.

United States.—In the United States the principles of the English common law as to infancy prevail, generally the most conspicuous variations being those affecting the age at which women attain majority. In many States this is fixed at 18. There is some diversity of practice as to the age at which a person can make a will of real or personal estate.

INFANTE, a title of the sons of the sovereigns of Spain and Portugal, the corresponding *infanta* being given to the daughters. (From Lat. *infans*, young child.) The title is not borne by the eldest son of the king of Spain, who is prince of Asturias, *II principe de Asturias*. While a son or a daughter of the sovereign of Spain is by right infante or infanta of Spain, the title, alone, is granted to other members of the blood royal by the sovereign.

INFANTICIDE. In sharp contrast to the modern anxiety to lessen child mortality, a feature due to the ethical advance of civilization, is the extent, as vouched for by sound historical evidence and by the direct observation of cultures in modern times, of the practice of infanticide or of putting new-born infants to death or of allowing them to die.

Thus it is recorded of the Nandi that "children are buried alive in cow-dung if they cry in their mother's womb or if at birth they present their legs first, or are born with teeth, as these events are considered unlucky. Children who are blind or badly deformed, and illegitimate children, *i.e.*, the offspring of unmarried girls, are likewise made away with at birth." From every quarter of the world, from simple nomadic peoples to settled agriculturalists comes evidence of similar practices, supported by similar reasons. The horror of the abnormal explains many of the cases. Breaches of the rules regulating sexual intercourse (an element present of necessity in all marriage systems whereby the status of the issue of the sexual union of the parents is established) may, as with the Nandi, lead to the immediate death of the offspring of an irregular union because, as is definitely certain in some instances, the ancestral spirits seeking reincarnation can only achieve their desire by regular marriage. They are ready therefore to punish matrimonial offences; and to avoid the dreadful consequences of rearing illegitimate children, in the community which the ancestors built up, the community is purged at once of their presence. In some cases a distinction is drawn between children born to parents who have neglected the formalities of marriage but are otherwise free to marry, and the offspring of those whose unions are forbidden by the law of exogamy (*q.v.*) or by some fundamental social ordinance. Illegitimate children of the first category are perhaps allowed to live, even to obtain membership of the community, to be legitimized by the subsequent formal marriage of their parents, while illegitimate children of the second category are put to death sometimes in a horrible manner, as if, it may be because, they are regarded as evil spirits. The birth of twins, as an abnormal occurrence, may be viewed as either an indication of future prosperity or of impending misfortune and social attitudes conform with the view taken in the community of the incident. Some welcome twins as proof of divine favour, others deem them akin to animals and therefore to be destroyed, while special treatment is often found to be applied to the cases where the twins are of opposite sex and therefore deemed to have had intercourse in violation of the law of exogamy.

Infanticide is sometimes practised for economic reasons—as when an Australian mother thinks she is unable to rear the new-born babe owing to there being a young child whom she is still feeding. A child of a few years of age is sometimes killed, to pass its strength on to a weakly elder child. Cases are known where a child has been killed in order that its soul may pass to a woman desirous of offspring. In India female infanticide was attributed to the custom of hypergamy (*q.v.*). To some superstition related to the social order is also attributed the rule of the Wataveta requiring the destruction of every child born to a woman after her daughter's marriage. The system of age-grades which forms an essential part of the structure of that tribe is perhaps the factor in this connection.

Children, especially the first-born, were killed to cure barrenness, to ensure health, good fortune and general fertility. Reincarnation beliefs play a part since if the son is the reincarnation

of his father, the son is put to death and the father lives. Again special sanctity, special virtue attached to the first-born and therefore the sacrifice of the first-born had special efficacy. In certain conditions the legitimacy of the first-born is dubious and his destruction may then be regarded as a special case of illegitimacy. There are many proofs of infanticide in religions possessing ethical potentialities such as Druidism and Semitism as well as in advanced communities such as Egypt, Greece and Rome.

It has been suggested that there is a social norm, a belief that "a particular number of children is the right number of children" (Carr-Saunders, *see bibl.*) and families in excess of the number approved by this convention may well have been kept to the norm by infanticide. How far among primitive peoples there is at times some deliberation as to whether a child shall be allowed to live, is not clear, but the evidence is thought to point to some semi-conscious adjustment of numbers.

That the destruction of weak, deformed and unsightly children at birth would have favourably affected the quality of the community is highly probable. Eugenic motives, however, were not present and the destruction of such children was conditioned by the superstitions attached to them.

Misinterpretation of imperfect data led McLennan in his pioneer work on *Human Marriage* (1865) to attribute an importance to infanticide as a factor in producing exogamy and thus shaping the social structure, which is now regarded as without warrant. The case of infanticide which he cited from Assam as due to the constant capture of girls taken by stronger villages as wives proved to be a case of "a superstition which condemned to death such as were born in a particular position" analogous to those cited above.

Carr-Saunders, *The Population Problem* (1922), in which, with a copious bibliography, there is a full discussion of the evidence for infanticide among hunting and fishing races, agricultural and historical races. *See also* E. Westermarck, *History of Human Marriage*, 6th ed. 3 vols. (1925); and *The Origin and Development of Moral Ideals* (1905); *Reports of the Census of India 1901 and 1911*. (X.)

Law.—Infanticide is murder or manslaughter according to the presence or absence of deliberation. The infant must be a human being in the legal sense; and "a child becomes a human being when it has completely proceeded in a living state from the body of its mother, whether it has breathed or not, and whether it has an independent circulation or not, and whether the navel-string is severed or not; and the killing of such a child is homicide when it dies after birth in consequence of injuries received before, during or after birth." A child in the womb or in the act of birth, though it may have breathed, is therefore not a human being, the killing of which amounts to homicide.

In 1922 by the Infanticide Act of that year it was provided that where a woman by any wilful act or omission causes the death of her newly born child, but at the time of the act or omission had not fully recovered from the effect of giving birth to such child, and by reason thereof the balance of her mind was then disturbed, she is, notwithstanding that the circumstances were such that the offence would have amounted to murder, to be found guilty of infanticide and may for such offence be dealt with and punished as if she had been guilty of the manslaughter of the child. What constitutes a "newly born child" was considered by the court of criminal appeal in *Rex v. O'Donoghue* (138 L.T. Rep. 240). The court declined to define the expression, but where a woman was charged with the murder of her child who was just above a calendar month old at the date of its death, the judge at the trial held that there was no evidence that the child was "newly born" within the meaning of the act, and the court held that his ruling was correct in law.

(W. DE B. H.)

INFANTRY, the collective name of soldiers who fight on foot. The word is derived ultimately from Lat. *infans*, infant, but it is not clear how the word came to be used to mean soldiers. The suggestion that it comes from a guard or regiment of a Spanish *infanta* about the end of the 15th century cannot be maintained in view of the fact that Spanish foot-soldiers of the time

were called *soldados* and contrasted with French *fantassins* and Italian *fanteria*. The *Oxford English Dictionary* suggests that a foot-soldier, being in feudal and early modern times the varlet or follower of a mounted noble, was called a boy (cf. *Knabe*, *garçon*, footman, etc., and *see VALET*).

I. HISTORICAL

Although it may be confidently asserted that the original fighting man was a foot-soldier, infantry was differentiated as an "arm" considerably later than cavalry; for when a new instrument of fighting (a chariot or a horse) was discovered, it was assimilated by relatively picked men, who *ipso facto* separated themselves from the mass or reservoir of men. How this mass itself ceased to be a mere residue and developed special characteristics; how, instead of the cavalry being recruited from the best infantry, cavalry and infantry came to form two distinct services; and how the arm thus constituted organized itself, technically and tactically, for its own work—these are the main questions that constitute the historical side of the subject. It is obvious that the "residue" was far the greatest part of the army; the history of the foot-soldier is practically identical with the history of soldiering.

The natural evolution of primitive fighting was towards the differentiation of the champion, the proved excellent fighting man, and to providing this man, on whom everything depended, with all assistance that better arms, armour, horse or chariot could give him. But suppose our champion slain, how are we to make head against the opposing champion? For long ages, we may suppose, the latter, as in the *Iliad*, slaughtered the sheep who had lost their shepherd, but in the end the "residue" began to organize itself, and to evolve a method of fighting which enabled it, or at least the better part of it, to oppose a firm and united front to the enemy's champions—in which term we include all selected men, whether horsemen, charioteers or merely specially powerful axemen and swordsmen. But once the individual had lost his commanding position, the problem presented itself in a new form—how to ensure that every member of the group did his duty by the others—and the solution of this problem for the condition of the ancient hand-to-hand struggle marks the historical beginning of infantry tactics.

The Phalanx and the Legion.—Gallic warriors bound themselves together with chains. The Greeks organized the city state, which gave each small army solidarity and the sense of duty to an ideal, and the phalanx in which the file-leaders were in a sense champions yet were made so chiefly by the unity of the mass. But the Romans went further. Besides developing solidarity and a sense of duty, they improved on this conception of the battle to such a degree that as a nation they may be called the best tacticians who ever existed. They split the mass of combatants into three bodies, of which the first, formed of the youngest and most impressionable men, was engaged at the outset, the rest, more experienced men, being kept out of the turmoil. This is the very opposite of the "champion" system. Those who would have fled after the fall of the champions are engaged and "fought out" before the champions enter the area of the contest, while the champions, who possess in themselves the greatest power of resisting and mastering the instinct of self-preservation, are kept back for the moment when ordinary men would lose heart.

It might be said with perfect justice that without infantry there would never have been discipline, for cavalry began and continued as a crowd of champions. Discipline, which created and maintained the intrinsic superiority of the Roman legion, depended first on the ideal of patriotism. This was ingrained into every man from his earliest years and expressed in a system of rewards and punishments which took effect from the same ideal, in that rewards were in the main honorary in character (mural crowns, etc.), while no physical punishment was too severe for the man who betrayed, by default or selfishness, the cause of Rome. Secondly, though every man knew his duty, not every man was equal to doing it, and in recognition of this fact the Romans evolved the system of three-line tactics in which the strong parts of the machine neutralized the weak. So closely knit were the parts of the system that not only did the decadence of patriotism

sap the legionary organization, but also the unsuitability of that organization to new conditions of warfare reacted unfavourably, even disastrously, on the *moral* of the nation. Between them, the Roman infantry fell from its proud place, and whereas in the Republic it was familiarly called the "strength" (*robur*), by the 4th century A.D. it had become merely the background for a variety of other arms and corps. As the Roman *imperium* extended the burden of foreign service became too heavy for the ordinary citizen, the citizen-army ceased to exist, and the mere necessity for garrisoning distant lands threw the burden of service upon the professional soldier.

The Roman Imperial Army.—The natural consequence of this last was the uniform training of every man. There were no longer any primary differences between one cohort and another, and though the value of the three-line system in itself ensured its continuance, any cohort, however constituted, might find itself serving in any one of the three lines, *i.e.*, the *moral* of the last line was no better than that of the first. In brief, the old Roman organization was based on patriotism and experience, and when patriotism gave place to "egoism," and the experience of the citizen who spent every other summer in the field of war gave place to the formal training of the paid recruit, it died, unregretted either by the citizen or by the military chieftain. The latter knew how to make the army his devoted servant, while the former disliked military service and failed to prepare himself for the day when the military chief and the mercenary overrode his rights and set up a tyranny, and ultimately the inner provinces of the empire came to be called *inermes*—unarmed, defenceless—in contrast to the borderland where the all-powerful professional legions lay in garrison.

In these same frontier provinces the tactical disintegration of the legion slowly accomplished itself. Originally designed for the exigencies of the normal pitched battle on firm open fields, and even after its professionalization retaining its character as a large battle unit, it was soon fragmented through the exigencies of border warfare into numerous detachments of greater or less size, and when the military frontier of the empire was established, the legion became an almost sedentary corps, finding the garrisons for the blockhouses on its own section of the line of defence. Further, the old heavy arms and armour which had given it the advantage in wars of conquest—in which the barbarians, gathering to defend their homes, offered a target for the blow of an army—were a great disadvantage when it became necessary to police the conquered territory, to pounce upon swiftly moving bodies of raiders before they could do any great harm. Thus gradually cavalry became more numerous, and light infantry of all sorts more useful, than the old-fashioned linesman. To these corps went the best recruits and the smartest officers, the opportunities for good service and the rewards for it. The legion became once more the "residue."

The battle of Adrianople (*q.v.*), the "last fight of the legion," illustrates this. The frontal battle was engaged in the ordinary way, and the first line of the imperial army was fighting man to man with the front ranks of the Gothic infantry, when suddenly the armoured heavy cavalry of the Goths burst upon their flank and rear. There were no longer *Principes* and *Triarii* of the old Republican calibre, but only average troops, in the second and third lines, and they were broken at once. The first line felt the battle in rear as well as in front and gave way. Thereafter the victors, horse and foot, slaughtered unresisting herds of men, and on this day the infantry arm, as an arm, ceased to exist.

The Dark Ages.—Regular infantry was still maintained for siege, mountain and forest warfare. But the *robur*, the kernel of the line of battle, was gone, and though a few of the peoples that fought their way into the area of civilization in the dark ages brought with them the natural and primitive method of fighting on foot, these infantry nations, without any infantry system comparable to that of the Greeks and Romans, succumbed in turn to the crowd of mounted warriors—not for want of good military qualities, but for want of an organization which would have distributed their fighting powers to the best advantage. One has only to study the battle of Hastings to realize how completely

the infantry masses of the English slipped from the control of their leaders directly the front ranks became seriously engaged. For many generations after Hastings there was no attempt to use infantry as the kernel of armies, still less to organize it as such beforehand. Indeed, except in the Crusades, where men of high and of low degree alike fought for their common faith, and in sieges, where cavalry was powerless and the services of archers and labourers were at a premium, it became unusual for infantry to appear on the field at all.

In those days in truth the infantry was no more the army than to-day the shareholders of a limited company are the board of directors. They were deeply, sometimes vitally, interested in the result, but they contributed little or nothing to bringing it about, except when the opposing cavalries were in a state of moral equilibrium, and in these cases anything suffices—the appearance of camp followers on a "Gillies Hill," as at Bannockburn, or the sound of half-a-dozen trumpets—to turn the scale. Once it turned, the infantry of the beaten side was cut down unresistingly, while the more valuable prisoners were admitted to ransom.

Revival of Infantry.—But even this infantry contained within itself two half-smothered sparks of regeneration, the idea of *archery* and the idea of *communal militia*. Archery, in whatever form practised, was the one special form of military activity with which the heavy *gendarme* (whether he fought on horseback or dismounted) had no concern, in sharp contrast to the Byzantine army in its heyday and to the Mongols who inflicted such sharp lessons on European chivalry in the 13th century. Here therefore infantry had a special function, and so far ceased to be "residue." The communal militia was an early and inadequate expression of the town-spirit that was soon to produce the solid burgher militia of Flanders and Germany and after that the trained bands of the English cities and towns. It was under the influence of these two ideas or forces that infantry as an arm began once again, though slowly and painfully, to differentiate itself from the worthless "residue."

Courtrai.—The first true infantry battle since Hastings was fought at Courtrai in 1302, between the burghers of Bruges and a feudal army under Count Robert of Artois. The citizens, arrayed in heavy masses, and still armed with miscellaneous weapons, were careful to place themselves on ground difficult of access—dikes, pools and marshes—and to fasten themselves together, like the Gauls of old. Their van was driven back by the French crossbowmen, whereupon Robert of Artois, true feudal leader as he was, ordered his infantry to clear the way for the cavalry and without even giving them time to do so pushed through their ranks with a formless mass of gendarmerie. This, in attempting to close with the enemy, became immovably fastened in the mud. The citizens swarmed all round it and with spear, cleaver and flail destroyed it.

Crécy (*q.v.*) was fought forty-four years after Courtrai. Here the knights had open ground to fight on, and many boasted that they would revenge themselves. But they encountered not merely infantry, but infantry tactics, and were for the second, and not the last, time destroyed. The English yeomen had reached a level of self-discipline and self-respect which few even of the great continental cities had attained. They had, further, made the powerful long-bow (*see* ARCHERY) their own, and Edward I. had combined the shock of the heavy cavalry with the slow searching preparatory rain of arrows (*see* FALKIRK). That is, infantry tactics and cavalry tactics were co-ordinated by a general, and the special point of this is that instead of being, as in France, the unstable base of the so-called "feudal pyramid," infantry had become an *arm*, capable of offence and defence and having its own special organization, function in the line of battle and tactical method. This last, indeed, like every other tactical method, rested ultimately on the *moral* of the men who had to put it into execution. Archer tactics did not serve against the disciplined rush of Joan of Arc's gendarmerie, for the solidarity of the archer companies that tried to stop it had long been undermined.

The English Archer.—Yet we cannot overrate the importance of the archer in this period of military history. In the city militias solidarity had been obtained through the close personal relation-

ship of the trade guilds and by the elimination of the champion. Therefore, as every offensive in war rests upon boldness, these militias were essentially defensive, for they could only hope to ward off the feudal champion, not to outfight him (*see* LEGNANO). England, however, had evolved a weapon which no armour could resist, and a race of men as fully trained to use it as the gendarme was to use the lance. Crossbows indeed were powerful, and also handled by professional soldiers (*e.g.*, the Genoese at Crécy), but they were slow in action, six times as slow as the long bow, and the impatient gendarmerie generally became tired of the delay and crowded out or rode over the crossbowmen. The long bow gave them the power of killing without being killed, which the citizens' spears and maces and *voulges* did not. But like all missiles, arrows were a poor stand-by in the last resort if determined cavalry crossed the "beaten zone" and closed in, and besides pavises and pointed stakes the English archers were given the support of the knights, nobles and sergeants—the armoured champions—whose steady lances guaranteed their safety. Here was the real forward stride in infantry tactics. Archery had existed from time immemorial, and a mere technical improvement in its weapon could hardly account for its suddenly becoming the queen of the battlefield. The defensive power of the "dark impenetrable wood" of spears had been demonstrated again and again, but when the cavalry had few or no preliminary difficulties to face, the chances of the infantry mass resisting long-continued pressure was small. It was the combination of the two elements that made possible a Crécy and a Poitiers, and this combination was the result of the English social system which produced the *camaraderie* of knight and yeoman, champion and plain soldier. Fortified by the knight's unshakable steadiness, the yeoman handled his bow and arrows with cool certainty and rapidity, and shot down every rush of the opposing champions. This was *camaraderie de combat* indeed, and in such conditions the strategic offensive was possible and even easy. The English conquered whole countries while the Flemish and German spearmen and *vougiere* merely held their own.

The Hundred Years' War.—But the war of conquest embodied in these decisive victories dwindled in its later stages to a war of raids. The feudal lord, like the feudal vassal, returned home and gave place to the professional man-at-arms and the professional captain. Ransom became again the chief object, and except where a great leader, such as Bertrand Du Guesclin, compelled the mercenaries to follow him to death or victory, a battle usually became a *mêlée* of irregular duels between men-at-arms. The war went on and on, the gendarmes thickened their armour, and the archers found more difficulty in penetrating it. Moreover, in raids for devastation and booty, the slow-moving infantryman was often a source of danger to his comrades. In this *guerrilla* the archer, though he kept his place, soon ceased to be the mainstay of battle. It had become customary since Crécy (where the English knights and sergeants were dismounted to protect the archers) for all mounted men to send away their horses before engaging. Here and there cavalry masses were used by such energetic leaders as the Black Prince and Du Guesclin, and more often a few men remained mounted for work requiring exceptional speed and courage—as for instance when thirty men-at-arms "cut out" the Captal de Buch from the midst of his army at Cocherel—but as a general rule the man-at-arms was practically a mounted infantryman, and when he dismounted he stood still.

Cavalry therefore became, in a loose sense of the word, infantry. But we are tracing the history not of all troops that stood on their feet to fight, but of infantry and the special tactics of infantry, and the period before and after 1370, when the moral foundations of the new English tactics had disappeared, and the personality of Du Guesclin gave even the bandits of the "free companies" an intrinsic, if slight, superiority over the invaders, is a period of deadlock. Solidarity, such as it was, had gone over to the side of the heavy cavalry. But the latter had deliberately forfeited their power of forcing the decision by fighting on foot, and the English archer, the cadre of the English tactical system, though diminished in numbers, prestige and importance, held to existence and survived the deadlock. Infantry of that type indeed could never return to the "residue" state, and it only needed a fresh moral

impetus, a Henry V., to set the old machinery to work again for a third great triumph. But again, after Agincourt, the long war lapsed into the hands of the soldiers of fortune, the basis of Edward's and Henry's tactics crumbled, and, under Joan of Arc, the French cavalry rode down the stationary masses of the English, lances and bowmen alike.

The net result of the Hundred Years' War therefore was to re-establish the two arms, cavalry and infantry, side by side, the one acting by shock, and the other by fire. The lesson of Crécy was "prepare your charge before delivering it," and for that purpose great bodies of infantry armed with bows, arblasts and hand-guns were brought into existence in France. When the French king in 1448 put into force the "lessons of the war" and organized a permanent army, it consisted in the main of heavy cavalry (knights and squires in the *ordonnance* companies, soldiers of fortune in the paid companies) and archers and arblasters (*francs-archers* recruited nationally, arblasters as a rule mercenaries, though largely recruited in Gascony). To these *armes de jet* were added, in ever-increasing numbers, hand firearms. Thus the "fire" principle of attack was established, and the defensive principle of "mass" relegated to the background. In such circumstances cavalry was of course the decisive arm, and the reputation of the French gendarmerie was such as to justify this bold elimination of the means of passive defence. This tendency of the French military temperament reappears at almost every stage in the history of armies.

Burgher Militias.—The foot-soldier of Germany and the Low Countries had followed a different line of development. Here the rich commercial cities scarcely concerned themselves with the quarrels or revolts of neighbouring nobles, but they resolutely defended their own rights against feudal interference, and enforced them by an organized militia, opposing the strict solidarity of their own institutions to the prowess of the champion who threatened them. The struggle was between "you shall" on the part of the baron and "we will not" on the part of the citizens, the offensive *versus* the defensive in the simplest and plainest form. The latter was a policy of unbreakable squares, and wherever possible, strong positions as well. Sometimes the citizens, sometimes the nobles gained the day, but the general result was that steady infantry in proper formation could not be ridden down, and as yeomen-archers of the English type to "prepare" the charge were not obtainable from amongst the serf populations of the countryside, the problem of the attack was, for Central Europe, insoluble.

The Wagenburg.—The unbreakable square took two forms, the *wagenburg* with artillery, and the infantry mass with pikes. The first was no more, in the beginning, than an expedient for the safe and rapid crossing of wider stretches of open country than would have been possible for dismounted men, whom the cavalry headed off as soon as they ventured far enough from the shelter of walls. The men rode not on horses but on carriages, and the carriages moved over the plains in laager formation, the infantrymen standing ready with halbert and *voulge* or short stabbing spear, and the gunners crouching around the long barrelled two-pounders and the *ribaudequins*—the early machine guns—which were mounted on the wagons. These *wagenburgen* combined in themselves the due proportions of mobility and passive defence, and in the skilled hands of Ziska they were capable of the boldest offensive. But such a tactical system depended first of all on drill, for the armoured cavalry would have crowded through the least gap in the wagon line, and the necessary degree of drill in those days could only be attained by an army which had both a permanent existence and some bond of solidarity more powerful than the incentive to plunder—that is, in practice, it was only attained in full by the Hussite insurgents. The cavalry too, learned its lesson, and pitted mobile three-pounders against the foot-soldiers' one- and two-pounders, and the *wagenburg* became no more than a helpless target. Thus when, not many years after the end of the Hussite wars, the Wars of the Roses eliminated the English model and the English tactics from the military world of Europe, the French system of fire tactics, masses of archers, arblasters and handgun-men, with some spearmen and halberdiers to stiffen them,

was left face to face with that of the Swiss and Landsknechts, the system of the "long pike."

The Swiss.—A series of victories ranging from Morgarten (1315) to Nancy (1477) had made the Swiss the most renowned infantry in Europe. Originally their struggles with would-be oppressors had taken the form, often seen elsewhere, of arraying solid masses of men, united in purpose and fidelity to one another rather than by any material or tactical cohesion. Like the men of Bruges at Courtrai, the Swiss had the advantage of broken ground and the still greater advantage of being opposed by reckless feudal cavalry. Their armament at this stage was not peculiar—voulges, gisarnes, halberts and spears—though they were specially adept in the use of the two-handed sword. But as time went on the long pike (said to have originated in Savoy or the Milanese about 1330) became more and more popular until at last on the verge of their brief ascendancy (about 1475–1515) the Swiss armed as much as one quarter of their troops with it. The use of firearms made little or no progress amongst them. But in a very few years after the Swiss nation had become soldiers of fortune *en masse*, the more open lands of Swabia entered into serious and bitter competition with them. From these lands came the Landsknechts, whose order was as strong as, and far less unwieldy than, that of the Swiss, whose armament included a far greater proportion of firearms, and who established a regimental system that left a permanent mark on army organization. The Landsknecht was the prototype of the infantryman of the 16th and 17th centuries, but his right to indicate the line of evolution had to be wrung from many rivals.

The Long Pike.—The year 1480 was a turning point in military history. Within the three years preceding it the battles of Nancy and Guinegate had destroyed both the old feudalism of Charles the Bold and the new cavalry tactics of the French gendarmerie. The former was an anachronism, while the latter, when the great wars came to an end and there was no longer either a national impulse or a national leader, had lapsed into the old vices of ransom and plunder. With these, on the same fields, the *franc-archer* system of infantry tactics perished ignominiously. It rested, as we know, on the principle that the fire of the infantry was to be combined with and completed by the shock of the gendarmerie, and when the latter were found wanting as at Guinegate, the masses of archers and arblasters were swept away by the charge of some heavy battalions of Swabian and Flemish pikes. Guinegate was the début of the Landsknecht infantry as Nancy was that of the Swiss, and the lesson could not be misread. Louis XI. indeed hanged some of his *franc-archers* and dismissed the rest, and in their place raised "bands" of regular infantry, one of which bore for the first time the historic name of *Picardie*. But these "bands" were not self-contained. Armed for the most part with *armes de jet* they centred on the 6,000 Swiss pikemen whom Louis XI., in 1480, took into his service, and for nearly fifty years thereafter the French foot armies are always composed of two elements, the huge battalions of Swiss or Landsknechts, armed with the long pike, and for their support and assistance, French and mercenary "bands." The term *Landsknecht* was not confined to the right bank of the Rhine. The French *lansquenets* came largely from Alsace, according to General Hardy de Perini. In the Italian wars Francis I. had in his service a famous corps called the "black bands" which was recruited in the lower Rhine countries.

The Italian Wars, 1494–1525.—The Italian wars of 1494 to 1544, in which the use of "fire" and shock was readjusted to meet the conditions created by firearms, were the nursery of modern infantry. The combinations of Swiss, Landsknechts, Spanish *tercios* and French "bands" that figured on the battlefields of the early 16th century were infinitely various. But it is not difficult to find a thread that runs through the whole.

The essence of the Swiss system was solidity. They arrayed themselves in huge oblongs of 5,000 men and more, at the corners of which, like the tower bastions of a 16th-century fortress, stood small groups of arquebusiers. The Landsknechts and the Romagnols of Italy, imitated and rivalled them, though as a rule developing more front and less depth. At this stage solidity was everything and fire-power nothing. At Fornuovo (1495) the mass of

arquebusiers and arblasters in the French army did little or nothing; it was the Swiss who were *l'espérance de l'ost*. At Agnadello or Vaila in 1509 the ground and the "encounter-battle" character of the engagement gave special chances of effective employment to the arquebusiers on either side. Along the front the Venetian marksmen, secure behind a bank, picked off the leaders of the enemy as they came near. On the outer flank of the battle the bands of Gascon arquebusiers, which would otherwise have been relegated to an unimportant place in the general line of battle, lapped round the enemy's flank in broken ground and produced decisive effect. But this was only an afterthought of the king of France and Bayard. In the rest of the battle the huge masses of Swiss pikes were thrown upon the enemy much as the old feudal cavalry had been, regardless of ditches, orchards, and vineyards.

Then for a moment the problem was solved, or partially solved, by the artillery. Thus by degrees a very numerous and exceedingly handy light artillery—"carts with gonnies," as they were called in England—came into play on the Italian battlefields, and took over from the dying *franc-archer* system the work of preparing the assault by fire. At Ravenna (*q.v.*) (1512), the fire action of the new artillery was extraordinarily murderous, ploughing lanes in the immobile masses of infantry. At Marignan (*q.v.*) the French gendarmerie and artillery, closely and skilfully combined, practically destroyed the huge masses of the Swiss, and so completely had "infantry" and "fire" become separate ideas that on the third day of this tremendous battle we find even the "bands of Piedmont" cutting their way into the Swiss masses.

The Spanish Infantry and the Arquebus.—But from this point the lead fell into the hands of the Spaniards. These were originally swift and handy light infantry, capable, like the Scottish Highlanders at Prestonpans and Falkirk long afterwards, of sliding under the forest of pikes and breaking into the close-locked ranks with buckler and stabbing sword. For troops of this sort the arquebus was an ideal weapon, and the problem of self-contained infantry was solved by Gonsalvo de Cordoba, Pescara and the great Spanish captains of the day by intercalating small closed bodies of arquebusiers with rather larger, but not inordinately large, bodies of pikes. These arquebusiers formed separate, fully organized sections of the infantry regiment. In close defence they fought on the front and flanks of the pikes, but more usually they were pushed well to the front independently, their speed and excellent fire discipline enabling them to do what was wholly beyond the power of the older type of firing infantry—to take advantage of ground, to run out and re-open fire during a momentary pause in the battle of lance and pike, and to run back to the shelter of their own closed masses when threatened by an oncoming charge. When this system of tactics was consecrated by the glorious success of Pavia (1525), the "cart with gonnies" vanished and the system of fighting everywhere and always "at push of pike" fell into the background.

By 1550 infantry had ceased to be an auxiliary arm. It contained within itself, and (what is more important) within its regimental units, the power of fighting effectively and decisively both at close quarters and at a distance. It had, further, developed a permanent regimental existence, both in Spain and in France, and in the former country it had progressed so far from the "residue" state that young nobles preferred to trail a pike in the ranks of the foot to service in the gendarmerie or light horse. The service battalions were kept up to war strength by the establishment of depôts and the preliminary training there of recruits.

The wars in which this system was evolved were wars for prestige and aggrandizement. But the wars of religion raised questions of life and death for the Frenchmen of either faith, and thus endowed operations with a new decisive spirit. Hence the relatively immobile "battalion" of pikes diminishes in importance and the arquebusiers and musketeers grow more and more efficient. Armies, too, became smaller, and marched more rapidly. Encounter battles became more frequent than "pitched" battles, and in these the musketeer was at a great advantage. Thus by 1600 the proportions between pikes and musketeers in the French army had come to be 6 pikes to 4 muskets or arquebuses, and the

bataillon de combat or brigade was normally no more than 1,200 strong. In the Netherlands, however, the war of consciences was fought out between the best regular army in the world and burgher militias. Even the French *fantassins* were second in importance to the Spanish *soldados*. The latter continued to hold the pre-eminent position they had gained at Pavia. They improved the arquebus into the musket, a heavier and much more powerful weapon (fired from a rest) which could disable a horse at 500 paces.

Alva.—At this moment the professional soldier was at the high-water mark of his supremacy. The musket was too complicated to be rapidly and efficiently used by any but a highly trained man; the pike, probably because it had now to protect two or three ranks of "shot" in front of the leading rank of pikemen, as well as the pikemen themselves, had grown longer (up to 18 ft.); and drill and manoeuvre had become more important than ever, for in the meantime cavalry had mostly abandoned the massive armour and the long lance in favour of half-armour and the pistol, and their new tactics made them both swifter to charge groups of musketeers and more deadly to the solid masses of pikemen. This superiority of the regular over the irregular was most conspicuously shown in Alva's war against the Netherlands patriots. Desperately as the latter fought, Spanish captains did not hesitate to attack patriot armies ten times their own strength. If once or twice this contempt led them to disaster, the normal battle was of the Jemmingen type—seven *soldados* dead and seven thousand rebels.

Such results as these naturally confirmed the "Spanish system" of tactics. The Dutch themselves, when they evolved reliable field armies, copied it with few modifications, and by degrees it was spread over Europe by the professional soldiers on both sides. The French, however, with their smaller battalions and more rapid movements were inclined to disparage both the cuirass and the pike, and only unwillingly hampered themselves with the long heavy Spanish musket, which had to be fired from a rest. In 1600, nearly fifty years after the introduction of the musket, this most progressive army still deliberately preferred the old light arquebus, and only armed a few selected men with the larger weapons. On the other hand, the Spaniards, though supreme in the open, had for the most part to deal with desperate men behind fortifications. Fighting, therefore, chiefly at close quarters with a fierce enemy, and not disposing either of the space or of the opportunity for "manoeuvre-battles," they sacrificed all their former lightness and speed, and clung to armour, the long pike and the heavy 2½ oz. bullet. But during the 17th century solidity, and the powers of passive resistance were, little by little, replaced by a more offensive armament and faculty, until at last the long pike disappeared altogether and the firearm, provided with a bayonet, was the uniform weapon of the foot-soldier. As far as France was concerned, it was a natural evolution. But the acceptance of the principle by the rest of the military world, imposed by the genius of Gustavus Adolphus, was rather revolution than evolution.

Gustavus Adolphus.—In the army which Louis XIII. led against his revolted barons of Anjou in 1620, the old regiments seem to have marched in an open chequer-wise formation of companies which is interesting not only as a deliberate imitation of the Roman legion (all soldiers of that time, in the prevailing confusion of tactical ideas, sought guidance in the works of Xenophon, Aelian and Vegetius), but as showing that flexibility and handiness was not the monopoly of the Swedish system that was soon to captivate military Europe. But the generals of the Thirty Years' War who were trained in the Spanish school formed their infantry into large battalions (generally a single line of masses). Experience certainly gave the troops that used these unwieldy formations a relatively high manoeuvring capacity, for Tilly's army at Breitenfeld (*q.v.*) "changed front half-left" in the course of the battle itself. But the manoeuvring power of the Swedes was higher still. Each party represented one side of the classical revival, the Swedes the Roman three-line manipular tactics, the Imperialists and Leaguers those of the Greek line of phalanxes. The former, depending as it did on high *moral* in the individual

foot-soldier, was hardly suitable to such a congeries of mercenaries as those that Wallenstein commanded, and in the later stages of the Thirty Years' War, when the old native Swedish and Scottish brigades had been annihilated, the Swedish infantry was little if at all better than the rest.

But its tactical system, sanctified by victory, was eagerly caught up by military Europe. The musket, though it had finally driven out the arquebus, had been lightened by Gustavus Adolphus so far that it could be fired without a rest. Rapidity in loading had so far improved that a company could safely be formed six deep instead of ten, as in the Spanish and Dutch systems. Its fire power was further augmented by the addition of two very light field-guns to each battalion; these could inflict loss at twice the effective range of the shortened musket. Above all, Gustavus introduced into the military systems of Europe a new discipline based on the idea of exact performance of duty, which made itself felt in every part of the service, and was a welcome substitute for the former easy-going methods of regimental existence. The adoption of Swedish methods indeed was facilitated by the disrepute into which the older systems had fallen. Courage the mercenary certainly possessed, but his individual sense of honour, code of soldierly morals, and sometimes devotion to a particular leader did not compensate for the absence of a strong motive for victory and for his general refractoriness in matters of detail, such as march-discipline and punctuality, which had become essential since the great Swedish king had reintroduced order, method and definiteness of purpose into the conduct of military operations.

The Great Rebellion.—The problem of combining the maximum of fire power with the maximum of control over the individual firer was not fully solved until 1740, but the necessity of attempting the problem was realized from the first. In the Swedish army, before it was corrupted by the atmosphere of the Thirty Years' War, duty to God and to country were the springs of the punctual discipline, in small things and in great, which made it the most formidable army, unit for unit, in the world. In the English Civil War (in which the adherents of the "Swedish system" from the first ousted those of the "Dutch") the difficulty was more acute, for although the mainsprings of action were similar, the technical side of the soldier's business—the regimental organization, drill and handling of arms—had all to be improvised. Now in the beginning the Royalist cavalry was recruited from "gentlemen that have honour and courage and resolution"; later, Cromwell raised a cavalry force that was even more thoroughly imbued with the spirit of duty, "men who made some conscience of what they did," and throughout the Civil War, consequently, the mounted arm was the queen of the battlefield.

The Parliamentary foot too "made some conscience of what it did," more especially in the first years of the war. But its best elements—the drilled townsmen—were rather of a defensive than of an offensive character; towards the close of the struggle, when the foot on both sides came to be formed of professional soldiers, the defensive element decreased, as it had decreased in France and elsewhere. The war was like Gustavus's German campaign, one of rapid and far-ranging marches, and the armoured pikeman had either to shorten his pike and to cast off his armour or to be left at home with the heavy artillery (*see Firth's Cromwell's Army*, ch. iv.). Fights at "push of pike" were rare enough to be specially mentioned in reports of battles.

Disuse of the Pike.—A small proportion of pikes was still held to be necessary by experienced soldiers, for as yet the socket bayonet had not been invented, and while there was still cavalry in Europe that could be trusted to ride home, the development of fire power was everywhere hindered by the necessity of self-defence. On the other hand the hitherto accepted defensive means militated against efficiency in many ways, and about 1670, when Louis XIV. and Louvois were fashioning the new standing army that was for fifty years the model for Europe, the problem was how to improve the drill and efficiency of the musketeers so far that the pikes could be reduced to a minimum. In 1680 the firelock was issued instead of the matchlock to all grenadiers and to the four best shots in each French Company. The bayonet—in its primitive form merely a dagger that was fixed into the muzzle of

the musket—was also introduced, and the pike was shortened. The proportion of pikes to muskets in Henry IV.'s day, 2 to 1 or 3 to 2, and in Gustavus's 2 to 3, had now fallen to 1 to 3.

The day of great causes that could inspire the average man with the resolution to conquer or die was, however, past, and the "shallow order" (*l'ordre mince*), with all its demands on the individual's sense of duty, had become an integral part of the military system. How then was the sense of duty to be created? Louis and Louvois and their contemporaries sought to create it by taking raw recruits in batches, giving them a consistent training, quartering them in barracks and uniforming them. Henceforward the soldier was not a unit, self-taught and free to enter the service of any master. He had no existence as a soldier apart from his regiment and within it he was taught that the regiment was everything and the individual nothing. Thus by degrees the idea of implicit obedience to orders and of *esprit de corps* was absorbed. But the self-respecting Englishman or the quick ardent Frenchman was not the best raw material for quasi-automatic regiments, and it was not until an infinitely more rigorous system of discipline was applied to an unimaginative army that the full possibilities of this enforced sense of duty were realized.

Methods of Fire Before 1740.—The method of delivering fire originally used by the Spaniards, in which each man in succession fired and fell back to the rear of the file to reload, required for its continued and exact performance a degree of coolness and individual smartness which was probably rarely attained in practice. This was not of serious moment when the "shot" were simple auxiliaries, but when under Gustavus the offensive idea came to the front, and the bullets of the infantry were expected to do something more than merely annoy the hostile pikemen, a more effective method had to be devised. First, the handiness of the musket was so far improved that one man could reload while five, instead of as formerly ten, fired. Then, as the enhanced rate of fire made the file-firing still more disorderly than before, two ranks and three were set to fire "volleys" or "salvees" together, and before 1640 it had become the general custom for the musketeers to fire one or two volleys and then, along with the pikemen, to "fall on."

The Bayonet.—With the decay of cavalry methods and *moral* the adoption of the flintlock musket and the invention of the socket bayonet (the fixing of which did not prevent fire being delivered), all reason for retaining the pike vanished, and from about 1700 the invariable armament of infantry became the musket and bayonet. The manner of employing the weapons, however, changed but slowly. But the idea of "push of pike" remained, the bayonet (as at Marsaglia) taking the place of the pike, and musketry methods were still and throughout the War of the Spanish Succession somewhat half-hearted and tentative.

Linear Tactics.—Meanwhile the tactics of armies had been steadily crystallizing into the so-called "linear" form, which, as far as concerns the infantry, was simply two long lines of battalions (three, four or five deep) and gave the utmost possible development to fire-power. The object of the "line" was to break or beat down the opposing line in the shortest possible time, whether by fire action or shock action, but fire action was only decisive at so short a range that the principal volley could be followed immediately by a charge over a few score paces at most and the crossing of bayonets. Fire was, however, effective at ranges outside charging distance, especially from the battalion guns, and however the decision was achieved in the end, it was necessary to cross the zone between about 300 yd. and 50 yd. range as quickly as possible. It was therefore the business of the regimental officer to force his men across this zone before fire was opened. If, as Catinat recommended, decisive range was reached with every musket loaded and the troops well in hand, their fire when finally it was delivered might well be decisive. But in practice this rarely happened, and though here and there such expedients as a skirmishing line were employed to assist the advance by disturbing the enemy's fire the most that was hoped by the average colonel or captain was that in the advance fire should be opened as late as possible and that the officers should strive to keep in their hands the power of breaking off the fire-

fight and pushing the troops forward again. The linear system rested on the principle that the maximum weight of controlled fire at short range was decisive, and the practical problem of infantry tactics was how to obtain this. The question of fire *versus* shock had been answered in favour of the former, and henceforward for many years the question of fire *versus* movement held the first place. The purpose was settled, and it remained to discover the means.

This means was Prussian fire-discipline, which was elaborated by Leopold of Dessau and Frederick William I., and practically applied by Frederick the Great. It consisted first in the combination, instead of the alternation, of fire and movement, and secondly in the thorough efficiency of the fire in itself. But both these demanded a more stringent and technically more perfect drill than had ever before been imagined, or, for that matter, has ever since been attained.

Prussian Fire Discipline, 1740.—On approaching the enemy the marching columns of the Prussians, which were generally open columns of companies 4 deep, wheeled in succession to the right or left (almost always to the right) and thus passed along the front of the enemy at a distance of 800–1,200 yd. until the rear company had wheeled. Then the whole together (or in the case of a deployment to the left, in succession) wheeled into line facing the enemy. These movements, if intervals and distances were preserved with proper precision, brought the infantry into two long well-closed lines, and parade-ground precision was actually attained, thanks to remorseless drilling and to the re-introduction of the march in step to music. Of course such movements were best executed on a firm plain, and as far as possible the attack and defence of woods and villages was left to light infantry and grenadiers. But even in marshes and scrub, the line managed to manoeuvre with some approach to the precision of the barrack square¹. This precision allowed Frederick to take risks that no former commander would have dared to take culminating in the oblique order attack of Leuthen (*q.v.*). With it was bound up a fire discipline that was more extraordinary than any perfection of manoeuvre. Before Hohenfriedberg the king gave orders that *pelotonfeuer* was to be opened at 200 paces from the enemy and continued up to 30 paces, when the line was to fall on with the bayonet. The possibility of this combination of fire and movement was the work of Leopold, who gave the Prussian infantry iron ramrods, and by sheer drill made the soldier a machine capable of delivering (with the flintlock muzzle-loading muskets, be it observed) five volleys a minute. This *pelotonfeuer* or company volleys replaced the old fire by ranks practised in other armies. Fire began from the flanks of the battalion, which consisted of eight companies (for firing, 3 deep). When the right company commander gave "fire," the commander of No. 2 gave "ready," followed in turn by other companies up to the centre. The same process having been gone through on the left flank, by the time the two centre companies had fired the two flank companies were ready to recommence, and thus a continuous series of rolling volleys was delivered, at one or two seconds' interval only between companies. In attack this fire was combined with movement, each company in turn advancing a few paces after "making ready." In the advance of the deployed line the special Prussian fire-discipline gave Frederick an advantage of five shots to two against all opponents. The bayonet-attack, if the rolling volleys had done their work, was merely "presenting the cheque for payment" as a modern German writer puts it. The cheque had been drawn, the decision given, in the fire-fight.

Leuthen.—For some years this method of infantry training gave the Prussians a decisive superiority in whatever order they fought. But their enemies improved and also grew in numbers, while the Prussian army's resources were strictly limited. Thus in the Seven Years' War, after the two costly battles of Prague and Kolin (1757) especially, it became necessary to manoeuvre with the object of bringing the Prussian infantry into

¹About this time there was introduced, for resisting cavalry, the well-known hollow battalion square, which, replacing the former masses of pikes, represented up to the most modern times the defensive as the line or column represented the offensive formation of infantry.

contact with an equal or if possible smaller portion of the enemy's line. If this could be achieved, victory was as certain as ever, but the difficulties of bringing about a successful manoeuvre were such that the classical "oblique order" attack was only once completely executed. This was at Leuthen (Dec. 5, 1757), perhaps the greatest day in the history of the Prussian army. Frederick's object was to destroy the left of the Austrian army (which far outnumbered his own) before the rest of their deployed line of battle could change front to intervene. His method was to place his own line, by a concealed flank march, opposite the point where he desired to strike, and then to advance, not in two long lines but in échelon of battalions from the right (*see* LEUTHEN). The échelon was not so deep but that each battalion was properly supported by the following one on its left (100 paces distance), and each, as it came within 200 yd. of the Austrian battalion facing it, opened its "rolling volleys" while continuing to advance; thus long before the left and most backward battalions were committed to the fight, the right battalions were crumbling the Austrian infantry units one by one from left to right.

One lesson of Leuthen that contemporary soldiers took to heart was that even a two-to-one superiority in numbers could not remedy want of manoeuvring capacity. It might be hoped that with training and drill an Austrian battalion could be made equal to a Prussian one in the front-to-front fight, and in fact, as losses told more and more heavily on Frederick's army as years went on, the specific superiority of his infantry disappeared. The last campaigns were indeed a war of positions, because Frederick had no longer the men available for forcing the Austrians out of them, and on many occasions he was so weak that the most passive defensive and the most elaborate entrenchments barely sufficed to save him. But whenever opportunity offered itself, the king sought a decisive success by bringing the whole of his infantry against part of the enemy's—the principle of Leuthen put in practice over a wider area with more elastic manoeuvre methods. In a battle each battalion or brigade fought as a unit in line, using company volleys and seeking the decision by fire.

Controversies and Developments, 1700–1790.—In this, and even in the most minute details of drill and uniform, military Europe slavishly copied Prussia for twenty years after the Seven Years' War. And withal, the period 1763–1792 is full of tactical and strategical controversies. The principal of these, as regards infantry, was that between "fire" and "shock" revived about 1710 by Folard, and about 1780 the American War of Independence complicated it by introducing a fresh controversy between *skirmishing* and *close order*. As to the first, in Folard's day as in Frederick's, fire action at close range was the deciding factor in battle, but in Frederick's later campaigns, wherein he no longer disposed of the old Prussian infantry and its swift mechanical fire-discipline, there sprang up a tendency to trust to the bayonet for the decision. If the (so-called) Prussian infantry of 1762 could in any way be brought to close with the enemy, it had a fair chance of victory owing to its leaders' previous dispositions, and then the advocates of "shock," who had temporarily been silenced by Mollwitz and Hohenfriedberg, again took courage. The ordinary line was primarily a formation for fire, and only secondarily or by the accident of circumstances for shock, and, chiefly perhaps under Saxe's influence, the French army had for many years been accustomed to differentiate between "linear" formations for fire and "columnar" for attack—thus reverting to 16th-century practice. While, therefore, the theoreticians pleaded for battalion columns and the bayonet or for line and the bullet, the practical soldier used both. Many forms of combined line and column were tried, but in France, where the question was most assiduously studied, no agreement had been arrived at when the advent of the skirmisher further complicated the issues.

In the early Silesian wars, when armies fought in open country in linear order, the outpost service was performed by irregular light troops, recruited from wild characters of all nations, who were also charged with the preliminary skirmishing necessary to clear up the situation before the deployment of the battle-army, but once the line opened fire their work was done and they cleared away to the flanks (generally in search of plunder). Later, light

infantry became more in demand and wider in scope. Yet there was no suggestion that light troops or skirmishers were capable of bringing about the decision in an armed conflict.

Light Infantry.—In the American War of Independence the line was pitted against light infantry in difficult country, and the British and French officers who served in it returned to Europe full of enthusiasm for the latter. Nevertheless, their light infantry was, unlike Frederick's, selected line infantry. The light infantry duties—skirmishing, reconnaissance, outposts—were grafted on to a disciplined training. At first these duties fell to the grenadiers and light companies of each battalion, but during the struggle in the colonies, the light companies of a brigade were so frequently massed in one battalion that in the end whole regiments were converted into light infantry. This combination of "line" steadiness and "skirmisher" freedom was the keynote of Sir John Moore's training system fifteen years later, and Moore's regiments, above all the 52nd, 43rd (now combined as the Oxfordshire Light Infantry) and 95th Rifles (Rifle Brigade), were the backbone of the British Army throughout the Peninsular War. Meantime the infantry organization and tactics of the old régime, elsewhere than in England, had been disintegrated by the flames of the French Revolution, and from their ashes a new system had arisen.

The French Revolution.—The controversialists of Louis XVI's time, foremost of whom were Guibert, Joly de Maizeroy and Menil Durand (*see* Max Jahns, *Gesch. d. Kriegswissenschaften*, vol. iii.), were agreed that shock action should be the work of troops formed in column, but as to the results to be expected from shock action, the extent to which it should be facilitated by a previous fire preparation, and the formations in which fire should be delivered (line, line with skirmishers or "swarms") discussion was so warm that it sometimes led to wrangles in ladies' drawing-rooms and meetings in the duelling field. The drill-book for the French infantry issued shortly before the Revolution was a compromise, which in the main adhered to the Frederician system as modified by Guibert, but gave an important place in infantry tactics to the battalion "columns of attack," that had hitherto appeared only spasmodically on the battlefields of the French army and never elsewhere. This, however, and the quick march (100 paces to the minute instead of the Frederician 75) were the only prescriptions in the drill-book that survived the test of a "national" war, to which within a few years it was subjected (*see* FRENCH REVOLUTIONARY WARS). The rest, like the "linear system" of organization and manoeuvre to which it belonged (*see* ARMY; CONSCRIPTION, etc.) was ignored, and circumstances and the practical troop-leaders evolved by circumstances fashioned the combination of close-order columns and loose-order skirmishers which constituted essentially the new tactics of the Revolutionary and Napoleonic infantry.

Tactical Evolution in France 1792–1807.—The process of evolution cannot be stated in exact terms but certain tendencies are easily discernible. The first tendency was towards the dissolution of all tactical links. The earlier battles were fought partly in line for fire action, partly in columns for the bayonet attack. Now the linear tactics depended on exact preservation of dressing, intervals and distances, and what required in the case of the Prussians years of steady drill at 75 paces to the minute was hardly attainable with the newly levied ardent Frenchmen marching at 100 to 120. Once, therefore, the line moved, it broke up into an irregular swarm of excited firers, and experience soon proved that only the troops kept out of the turmoil were susceptible of manoeuvre and united action. Thus from about 1795 onwards the forms of the old régime gave way to new ones in which the skirmishers are fewer and the closed troops more numerous, and the decision rests no longer with the fire of the leading units (which of course could not compare in effectiveness with the rolling volleys of the drilled line) but with the bayonets of the second and third lines—the latter being sometimes in line but more often, owing to the want of preliminary drill, in columns. The skirmishers tended again to become pure light infantry, whose rôle was to prepare, not to give, the decision, and who fought in a thin line, taking every advantage of cover and marks-

manship.

In sum, then, from 1792 to 1795 the fighting methods of the French infantry were, as they have been aptly called, "horde tactics." From 1796 onwards to the first campaigns of the Empire, on the other hand, there was an ever-growing tendency to combine skirmishers, properly so called, with controlled and well-closed bodies in rear, the first to prepare the attack to the best of their ability by individual courage and skill at arms, the second to deliver it at the right moment (thanks to their retention of manoeuvre formations), and with all possible energy (thanks to the cohesion, moral and material, which carried forward even the laggards). Even when in the long wars of the Empire the quality of the troops progressively deteriorated, infantry tactics within the regiment or brigade underwent no radical alteration. The actual formations were most varied, but they always contained two of the three elements, column, line and skirmishers. Column (generally two lines of battalions in columns of double-companies) was for shock or attack, line for fire-effect, and skirmishers to screen the advance, to scout the ground and to disturb the enemy's aim. Of these, except on the defensive (which was rare in a Napoleonic battle), the "column" of attack was by far the most important. The line formations for fire, with which it was often combined, rarely accounted for more than one-quarter of the brigade or division, while the skirmishers were still less numerous. Withal, these formations in themselves were merely fresh shapes for old ideas. The armament of Napoleon's troops was almost identical with that of Frederick's or Saxe's. Line, column and combinations of the two were as old as Fontenoy and were, moreover, destined to live for many years after Napoleon had fallen. "Horde tactics" did not survive the earlier Revolutionary campaigns. Wherein then lies the change which makes 1792 rather than 1740 the starting point of modern tactics?

Napoleon's Infantry and Artillery Tactics, 1807-1815.—

The answer, in so far as so comprehensive a question can be answered from a purely infantry standpoint, is that whereas Frederick, disposing of a small and highly finished instrument, used its manoeuvre power and regimental efficiency to destroy one part of his enemy so swiftly that the other had no time to intervene. Napoleon, who had numbers rather than training on his side, only delivered his decisive blow after he had "fixed" all bodies of the enemy which would interfere with his preparations—*i.e.*, had set up a physical barrier against the threatened intervention. This new idea manifested itself in various forms, strategic as well as tactical. As regards infantry the effect of it was revolutionary. Regiments and brigades were launched to the attack to compel the enemy to defend himself, and fought until completely dissolved to force him to use up his reserves. "*On s'engage partout et puis l'on voit*" is Napoleon's own description of his holding attack, which in no way resembled the "feints" of previous generations. The self-sacrifice of the men thus engaged enabled their commander to "see," and to mass his reserves opposite a selected point, while little by little the enemy was hypnotized by the fighting. Lastly, when "the battle was ripe" a hundred and more guns galloped into close range and practically annihilated a part of the defender's line. They were followed up by masses of reserve infantry, often more solidly formed at the outset than the old Swiss masses of the 16th century. If the moment was rightly chosen these masses, dissolved though they soon were into dense formless crowds, penetrated the gap made by the guns (with their arms at the slope) and were quickly followed by cavalry divisions to complete the enemy's defeat. Here, too, it is to be observed there is no true shock. The infantry masses merely "present the cheque for payment," and apart from surprises,

Perhaps a still more significant cause was that Napoleon as a tactician reveals himself as more scientist than artist. His victories owed more to superiority of method and scientific calculation than to superiority of art—expressed in stratagem and surprise. Unlike Hannibal, Scipio, Cromwell, Wellington and other great tactical artists throughout the greater part of his career he had, or his strategy gave him, the advantage of numbers. Thus he tended, and was able to expend this fund of man-power more freely in battle than others among the Great Captains, who used surprise and ground as a means both to economise, and to obtain the highest dividend from, their limited capital.—*Military Editor.*

ambushes and fights in woods and villages there are few recorded cases of bayonets being crossed in these wars. Napoleon himself said "*Le feu est tout, le reste peu de chose*," and though a mere plan of his dispositions suggests that he was the disciple of Folard and Menil Durand, in reality he simply applied "fire-power" in the new and grander form which his own genius imagined.

The problem, then, was not what it had been one hundred and fifty years before. The business of the attack was not to break down the passive resistance of the defence, but to destroy or to evade its fire-power. No attack with the bayonet could succeed if this remained effective and unbroken, and no resistance (in the open field at least) availed when it had been mastered or evaded. In Napoleon's army, the circumstance that the infantry was (after 1807) incapable of carrying out its own fire-preparation forced the task into the hands of the field artillery. In other armies the 18th-century system had been discredited by repeated disasters, and the infantry, as it became "nationalized," was passing slowly through the successive phases of irregular lines, "swarms," skirmishers and line-and-column formations that the French Revolutionary armies had traversed before them—none of them methods that in themselves had given decisive results.

The British Peninsular Infantry.—In all Europe the only infantry that represented the Frederician tradition and prepared its own charge by its own fire was the British. Eye-witnesses who served in the ranks of the French have described the sensation of powerlessness that they felt as their attacking column approached the line and watched it load and come to the present. The column stopped short, a few men cheered, others opened a ragged individual fire, and then came the volleys and the counter-attack that swept away the column. Sometimes this counter-stroke was made, as in the famous case of Busaco, from an apparently unoccupied ridge, for the British line, under Moore's guidance, had shaken off the Prussian stiffness, fought 2 deep instead of 3 and was able to take advantage of cover. The "blankness of the battlefield" that distinguished the South African and Manchurian Wars was characteristic of Wellington's battles from Vimeiro to Waterloo, in spite of close order and red uniforms. But these battles were of the offensive-defensive type in the main, and for various reasons this type could not be accepted as normal by the rest of Europe. Nonchalance was not characteristic of the eager national levies of 1813 and 1814, and the Wellington method of infantry tactics, though it had brought about the failure of Napoleon's last effort, was still generally regarded as an illustration of the already recognized fact that on the defensive the fire-power of the line, unless partly or wholly evaded by rapidity in the advance and manoeuvring power or mastered and extinguished by the fire-power of the attack, made the front of the defence impregnable. There was indeed nothing in the English tactics at Waterloo that, standing out from the incidents of the battle, offered a new principle of winning battles.

Infantry Methods, 1815-1870.—Thus the later Napoleonic battle became the model for military Europe, and infantry tactics retained, in Germany, Austria and Russia, the characteristic Napoleonic formations, lines of battalion or regimental columns, sometimes combined with linear formation for fire, and always covered by skirmishers. The moral power of the offensive "will to conquer" and the rapidity of the attack itself were relied upon to evade and disconcert the fire-power of the defence. If the attack failed to do so, the ranges at which infantry fire was really destructive were so small that it was easy for the columns to deploy or disperse and open a fire fight to prepare the way for the next line of columns. And after a careful study of the battle of the Alma, in which the British line won its last great victory in the open field, Moltke himself only proposed such modifications in the accepted tactical system as would admit of the troops being deployed for defence instead of meeting attack, as the Russians met it, in solid and almost stationary columns. Fire in the attack, in fact, had come to be considered as chiefly the work of artillery, and as artillery, being an expensive arm, had been reduced during the period of military stagnation following Waterloo, and was no longer capable of Napoleonic

feats, the attack was generally a bayonet attack pure and simple. Waterloo and the Alma were credited, not to fire-power, but to English solidity, and as Ardant du Picq observes, "All the peoples of Europe say 'no one can resist our bayonet attack if it is made resolutely'—and *all are right*. . . . Bayonet fixed or in the scabbard, it is all the same." But the means (moral and material) at the disposal of the defence for the purpose of mastering this resolution were, within a few years of the Crimean War, revolutionized by the general adoption of the rifle, the introduction of the breech-loader and the revival of the "nation in arms."

Thirty years before the Crimean War the flint-lock had given way to the percussion lock (*see GUN*), which was more certain in its action and could be used in all weathers. But fitting a copper cap on the nipple was not so simple a matter for nervous fingers as priming with a pinch of powder, and the usual rate of fire had fallen from the five rounds a minute of Frederick's day to two or three at the most. "Fire power" therefore was at a low level until the general introduction¹ of the rifled barrel, which while further diminishing the rate of fire, at any rate greatly increased the range at which volleys were effective. Artillery, the fire-weapon of the attack, made no corresponding progress, and even as early as the Alma and Inkerman (where the British troops used the Minié rifle) the dense columns had suffered heavily without being able to retaliate by "crossing bayonets." Fire power, therefore, though still the special prerogative of the defence, began to reassert its influence, and for a brief period the defensive was regarded as the best form of tactics. But the low rate of fire was still a serious objection. Many incidents in the American Civil War showed this, notably Fredericksburg, where the key of the Confederate position was held—against a simple frontal attack unsupported by effective artillery fire—by three brigades in line one behind the other, *i.e.*, by a six-deep firing line. No less force could guarantee the "inviolability of the front," and even when, in this unnatural and uneconomical fashion, the rate of fire was augmented as well as the effective range, a properly massed and well-led attack in column (or in a rapid succession of deployed lines) generally reached the defender's position, though often in such disorder that a resolute counterstroke drove it back again. The Americans fought over more difficult country and with less previous drill-training than the armies of the Old World. The fire power of the defence, therefore, that even in America did not always prevail over the resolution of the attack, entirely failed in the Italian war of 1859 to stop the swiftly moving well-drilled columns of the French professional army—and the Austrians were thus induced to abandon their new "defensive" doctrine and restore "bayonet tactics." But a revolution was at hand.

The Breech-loading Rifle.—In 1861 Moltke, discussing the war in Italy, wrote, "General Niel attributes his victory (at Solferino) to the bayonet. But that does not imply that the attack was often followed by a hand-to-hand fight. In principle, when one makes a bayonet charge, it is because one supposes that the enemy will not await it. . . . *To approach the enemy closely, pouring an efficacious fire into him*—as Frederick the Great's infantry did—is also a method of the offensive." This method was applicable at that time for the Prussians alone, for they alone possessed a breech-loading firearm. The needle-gun was a rudimentary weapon in many respects, but it allowed of maintaining more than twice the rate of fire that the muzzle-loader could give, and, moreover, it permitted the full use of cover, because the firer could lie down to fire without having to rise between every round to load. Further, he could load while actually running forward, whereas with the old arms loading not only required complete exposure but also checked movement. The advantages of the Prussian weapon were further enhanced, in the war against Austria, by the revulsion of feeling in the

Imperial army in favour of the pure bayonet charge in masses that had followed upon Magenta and Solferino.

With the stiffly drilled professional soldier of England, Austria and Russia the handiness of the new weapon could hardly have been exploited, for (in Russia at any rate) even skirmishers had to march in step. The Prussians were drilled nominally in accordance with regulations dating from 1812, and therefore suitable, if not to the new weapon, at least to the "swarm" fighting of an enthusiastic national army, but upon these regulations a mass of peace-time amendments had been superimposed, and in theory their drill was as stiff as that of the Russians. But, as in France in 1793–1796, the citizen composition of their army saved them from their regulations. Dietrich von Bülow's predictions of the future battle of "skirmishers" (meaning thereby a dense but irregular firing line) had captivated the younger school of officers, while King William and the veterans of Napoleon's wars were careful to maintain small columns (sometimes company columns of 240 rifles, but quite as often half-battalion and battalion columns) as a solid background to the firing line. Thus in 1866 (*see SEVEN WEEKS' WAR*), as Moltke had foreseen, the attacking infantry fought its way to close quarters by means of its own fire, and the bayonet charge again became, in his own words, "not the first, but the last, phase of the combat," immediately succeeding a last burst of rapid fire at short range and carried out by the company and battalion reserves in close order.

Infantry in the War of 1870.—Immediately after the Austrian overthrow at Königgrätz the French army was served out with a breech-loading rifle greatly superior in every respect to the needle gun, and after four years' tension France pitted breech-loader against breech-loader. In the first battles (*see WORTH and METZ: Battles*) the decision-seeking spirit of the "armed nation," the inferior range of the needle-gun as compared with that of the chassepot, and the recollections of easy triumphs in 1864 and 1866, all combined to drive the German infantry forward to within easy range before they began to make use of their weapons. Their powerful artillery would have sufficed of itself to enable them to do this (*see SEDAN*), had they but waited for its fire to take effect. But they did not, and they suffered accordingly. In these circumstances their formations broke up, and the whole attacking force dissolved into long irregular swarms. These swarms were practically composed only of the brave men, while the rest huddled together in woods and valleys. When, therefore, at last the firing line came within 400 or 500 yd. of the French, it was both severely tried and numerically weak, but, fortunately for it, the French counterstrokes were subjected to the fire of the German guns and were never more than locally and momentarily effective. More and more German infantry was pushed forward to support the firing line, and, like its predecessors, each reinforcement, losing most of its unwilling men as it advanced over the shot-swept ground, consisted on arrival of really determined men, and closing on the firing line pushed it forward, sometimes 20 yd., sometimes 100, until at last rapid fire at the closest ranges dislodged the stubborn defenders. Bayonets (as usual) were never actually used, save in sudden encounters in woods and villages. The decisive factors were, first the superiority of the Prussian guns, secondly, heavy and effective fire delivered at short range, and above all the high *moral* of a proportion of resolute soldiers who, after being subjected for hours to the most demoralizing influences, had still courage left for the final dash.

II. INFANTRY IN MODERN WAR

The net result of the Franco-German war on infantry tactics, so far as it can be summed up in a single phrase, was to transfer the fire-fight to the line of skirmishers. Henceforward the old and correct sense of the word "skirmishers" is lost, and their duties of feeling the way for the battle-formations came to be taken over by a lesser number of "scouts." But although the fire-fight on this line of scouts built up into a firing line, was established as the centre of gravity of the modern battle, a hot controversy sprang up over its form. This, in the early stages, became a contest between "drill" and "individualism." To many German officers the most indelible impression of the battlefield was what

¹Rifles had, of course, been used by corps of light troops (both infantry and mounted) for many years. The British Rifle Brigade was formed in 1800, but even in the Seven Years' War there were rifle-corps or companies in the armies of Prussia and Austria. These older rifles could not compare in rapidity or volume of fire with the ordinary firelock.

they called *Massen-Drückebergertum* or "wholesale skulking." The rest, who had perhaps in most cases led the brave remnant of their companies in the final assaults, believed that battles were won by the individual soldier and his rifle. The difference between the two may be said to lie in this, that the first sought a remedy, the second a method. The remedy was *drill*, the method *extended order*.

The extreme statement of the case in favour of drill pure and simple is to be found in the famous anonymous pamphlet *A Summer Night's Dream*, in which a return to the "old Prussian fire-discipline" of Frederick's days was offered as the solution of the problem, how to give "fire" its maximum efficacy. The other school, although closer akin to the reality of the fire-swept modern battlefield, under-rated the importance of control and instilled the idea that to teach the recruit to shoot and to work with other individuals in the squad or company, was as far as training could, or need, go. Disorder and crowding in the firing line was accepted, not as an unavoidable evil, but as a condition in which individuality had full play—a view that held much truth, but not the whole truth.

Between these extremes, official opinion, with the emperor William at its head, spent a few years in groping for close-order formations which admitted of control without vulnerability—a vain ideal even at that stage of the development of small arms, and ultimately formulated a compromise, combining the "drill" and teaching ideas in the German infantry regulations of 1888, which at last abolished those of 1812 with their multitudinous amendments. The necessity for "teaching" arose partly out of the new conditions of service and the relative rarity of wars. But it was still more the new conditions of fighting that demanded careful individual training. Of old, the professional soldier (other than the man belonging to light troops or the ground scout) was either situated out of danger, or so deep in battle that he became the unconscious agent of his inborn or acquired instincts. But the increased range of modern arms prolonged the time of danger, which was further prolonged by the increasing duration of battles.

Psychological Problems.—The psychological strain and problem created by this increased exposure to danger was further complicated by the enforced and inevitable dispersion of the troops while in the danger zone. Thus they stepped out of the control of their regimental leaders, and the higher commander lost the power to direct the fight according to a purposeful plan. In battle he could no longer proportion his effort to his ends, but only his means. Instead of being the driver of the battle-machine, with his hand on the throttle able to regulate the pressure, he was reduced to the rôle of stoker shovelling in more or less human fuel as he judged advisable. Military thought reconciled itself to this new conception in a remarkable spirit of resignation, and with a still more remarkable lack of research for fresh ways of reviving the craft of generalship. In default of this the only practicable alternative was to raise soldiery to a craft. If generals in the true sense could no longer be trained, the fighting man could at least be imbued in some degree with the faculties of generalship, so that he could control and direct himself when higher control and direction was released. Unfortunately, the tradition of "moulding" soldiers was too strong for the new training to have effective scope. This was merely soldered on to the old pattern frame. Man's natural instinct in a fight is "to kill without being killed," while the tendency of traditional military training has always been by stifling this natural instinct, to produce a man ready to let himself be killed—at the word of command. Such discipline of the instinct is undoubtedly a valuable quality. In situations of great danger the ordinary man is the slave of the unconscious, and his actions are determined mainly by his strongest natural instinct.

The very nature of late 19th-century armies tended to emphasize the importance of disciplining the instincts. For under conscription armies were no longer composed of the naturally adventurous, but of the more normal lovers of safety. By constant drill, however, they might be converted into danger-disregarding *automata*. There was, however, a weak point, and one accentuated by another modern condition—the increasing deadliness and range

of fire-weapons. However useful it may be to get men to advance automatically in face of danger, their usefulness ceases the moment they are dead. And as weapons developed, automatic men offered an easy target. Was it then a choice between two evils, or could a third course be found? The experience of many wars suggests that such an alternative existed. For at the end of any long war it has been found that men become cunning and skilful individual fighters, and although more wary do not lose unless of indifferent material their willingness to sacrifice themselves at the call of need. This is "reason" as against inborn or implanted instinct.

Tactical Training.—There is one form of training in peace which is aimed at the cultivation of reason—tactical training. It may be robbed of most of its utility by meaningless application, but fundamentally it is an appeal to the reason, just as drill in the opposite way is a development of the instinct. But when tactical training has been applied to men whose natural instinct of self-preservation has been drilled out of them, and replaced by a purely automatic instinct of self-sacrifice, it cannot hope to provide self-directed soldiers as an effective substitute for generals who have lost the power to direct their men.

After 1870 there was a great opportunity to take this new middle road. The war on both sides had furnished ample proof that drill-disciplined troops, once their acquired instinct had been uprooted by heavy initial losses, suffered a worse reaction into confusion, and even panic, than could possibly have occurred with soldiers whose reason had been educated. But military doctrine, spurred on by the conscriptive system, chose to continue on the old road which led them in 1914 to a still deeper pit. Drill was therefore maintained as the basis of all European military training. To maintain it was right; the error lay in maintaining it in this place and form. No organization, military or industrial, can dispense with drill, for it is, fundamentally, but the method of executing a movement repeatedly, so that it may develop into a habit, thereby enabling it to be carried out with the minimum expenditure of energy and the maximum of efficiency.

Battle Drill.—Executive skill of any kind owes much to habit. Thus the changed conditions of warfare made drill more necessary than ever—but in a new form. For drill is a fine cement, but a bad foundation. The enforced dispersion, due to fire, required a "battle drill" as a means of developing the swift self-controlled movements of widely extended units and of synchronizing the co-operative action of the scattered groups of skirmishers. Unfortunately for the solution of infantry problems "drill" and "close order" were commonly confused—as they still are 50 years later, owing largely to the fact that in the 1870 battles the dissolution of close order formations practically meant the end of control as control was then understood. Thus, dispersion was only tolerated as an unavoidable evil and European soldiers sought to mitigate its consequences by postponing the moment of dispersion as long as possible—instead of seeking a permanent cure by adapting drill to the needs of dispersion. As the years passed and the memories of the battlefield faded, there was a natural tendency to make the wish father to the thought and to believe—in face of the evidence of technical progress in fire-arms—that closer rather than looser formations could be used on the next battlefield. The German infantry regulations of 1906 aptly illustrated this spirit—"It must never be forgotten that the obligation of abandoning close order is an evil which can often be avoided. . . ."

As the memories of 1870 faded, the absence of bullets on the mimic battlefields of peace training lent impetus to the inevitable reaction which follows every step of progress. It is difficult to visualize bullets but easy to see men. Hence, those who direct and umpire field exercises in peace tend to base their verdict on a count by heads, and thus if a commander wishes to gain a favourable verdict he is almost driven to put in sufficient numbers of men to impress the observer that his attack has adequate "weight." Even if he is adjudged to suffer casualties, they are customarily calculated in proportion to his strength, whereas the more discriminating verdict of bullets penalises dense numbers out of all proportion to the original strength. The inevitable out-

come was that each successive training regulation issued between 1875 and 1914 tended to encourage greater density of numbers, while all the time in the armament factories fresh weapons were being produced to take an even greater toll of thickened targets.

Influence of Boer Tactics.—In the course of this unreal reaction there was however one interruption. In the South African War of 1899–1902 the soldiers of Europe were astonished to find the ill-organized and undrilled Boers more than holding their own against superior numbers of regular troops, by the deadliness of their shooting combined with the evasive mobility of their movements. Instances were known when 18 Boer marksmen were sufficient to repulse several British battalions. So deadly was the Boer fire that in self-preservation the British infantry were forced to make an abnormally early deployment into many successive lines of widely extended men.

For a year or two some of the European armies were inclined to flirt with "Boer tactics," but its "individualism" was repugnant to their traditions, made too shadowy a spectacle, and was difficult to apply to short-service conscript troops. Besides it had outwardly ended in defeat, however uneconomic to the nominal victors, and critics were quick to point out that its pure individualism had hampered co-operative effort so that its exponents had been unable to push home their opening success. From this, it was an easy conclusion that individualism itself was at fault. Hence European armies soon reverted to their old doctrines, and so far as any permanent change occurred it was derived from the modifications introduced by the British, and "extended order" became the rule for infantry in battle. The British practice in and immediately after the South African war was to deploy the whole body before the attack began into a deep series of lines, with intervals of ten to 20 paces between men. The rear lines were merely used to feed the first, or "firing" line. These long continuous lines however had shown themselves unable to produce any decisive effect and were essentially unmanageable. Opposing positions were nearly always taken by wide outflanking movements, and even so were found empty, as the rigidly extended frontal advance rarely succeeded in pinning down the defenders. This defect was plain to European tacticians, and they soon adopted the obvious remedy—that of reducing the intervals and holding the reserves in concentrated formations, instead of dispersing them into lines.

The real lesson—the surprising fire effect exerted by scattered Boers sitting on distant *kopjes*—was soon forgotten, most easily by those armies that had not experienced it personally. The British army suffered less than others from the reaction towards denser formations, because of its experience and because its constant preoccupation with colonial expeditions gave less chance for the effects of fire to fade from its memory. Its national bane was that of "lines" themselves, rather than dense ones in particular. Lines required long pauses to restore their alignment unless they were to dissolve in disorder; the units forming them were trained to wait for their neighbours and to avoid an exposed flank as a deadly danger; consequently, the pace of the line became the pace of its slowest unit—with a correspondingly prolonged exposure of the target. For a line of men, even an "extended" line, is one of the most visible of targets—a swathe of human corn calling the attention of the reaper. Its very symmetry makes it a cemetery.

Revival of the Napoleonic Attack.—On the continent the natural swing of the peace-time pendulum received an artificial impulse from the rehabilitation of the "Napoleonic attack" in the decade before 1914. In France, particularly, an influential school of military thought had for long devoted itself to a minute study of Napoleon's campaigns and correspondence with the idea of discovering the secret of his victories. Thereby they hoped to formulate a remedy by which the debilitated military body of France could recover from its 1870 collapse and gain new strength. Valuable results were attained, but mistakenly they sought to apply them to the technical sphere of tactics, instead of adapting the spirit of his principles to the conditions imposed by the introduction of accurate firearms. The progress made in timed shrapnel suggested the use of concentrations of shrapnel

fire to revive the deadly Napoleonic artillery preparation, and the infantry were to fulfil the rôle of the massed reserves which had poured through the breach thus made. Naturally, this conduced to greater density and was in turn accentuated by the propaganda of a new metaphysical school of military thought which was so obsessed with its discovery that the "will to conquer" is the soul of victory that it tended to forget that the human will, to be effective, must retain its habitation in the human body, and that human bodies are vulnerable to bullets.

The influence of this school grew when its leader and prophet, Colonel de Grandmaison, became chief of the Operations branch of the General Staff. The "security" aspect of the Napoleonic method was entirely overshadowed by the "audacity" form. De Grandmaison's text was that instead of waiting for the enemy to disclose his hand, "it is the quickness with which we engage the enemy that guarantees us against surprise, and the power of the attack which secures us against the enemy's manoeuvres." He summed up his theory by saying, "We must not recoil before this principle, of which only the form seems paradoxical: in the offensive, imprudence is the best of safeguards." The conclusion was that, whatever the rôle of a force or unit, there was only one mode of action—attack, which meant a headlong assault. The very simplicity of this theory combined with its appeal to the Frenchman's temperament—and its implicit tribute to the irresistibility of his spirit—to capture the imagination of the Army. Those who opposed it were derided and superseded, as "lacking in nerve." And the official doctrine was re-cast on the foundation that "the French Army, returning to its traditions, no longer knows any other law than the offensive. . . . All attacks are to be pushed to the extreme with the firm resolution to charge the enemy with the bayonet, in order to destroy him. . . . This result can only be obtained by bloody sacrifice. Any other conception ought to be rejected as contrary to the very nature of war."

Accordingly, the training of the infantry was directed to a discipline of the muscles, not of the intelligence, sacrificing initiative in order, by an incessant repetition, "to develop in the soldier the reflexes of obedience." The successive French tactical regulations issued during the 40 odd years of peace which separated the wars of 1870 and 1914, shed a curious light on the way the memory of pain fades—and still more the memory of its cause. Thus it came about that the first regulations of 1875 came nearest to the reality of 1914, whereas the last of the series was framed for a battlefield on which there were no bullets.

Emphasis on Fire Superiority.—If the German doctrine took hardly more account of the opposing fire, or of the progress in firearms, and was equally addicted towards density of formations, it laid more emphasis on the need of fire to help the assailants forward. This attitude is well exemplified in the German regulations of 1906 which defined the offensive as "transporting fire towards the enemy, if necessary to his immediate proximity"; the bayonet assault "confirms" it. As for the process of attack, the prescriptions may be summarized as follows—every attack was to begin with deployment into extended order, and the leading line was to advance as close to the enemy as possible before opening fire. In ground offering cover, the firing line should have practically its maximum density at the outset. In open ground, however, units were advanced one after the other till all were *in position*. It was on this position, called the "first fire position" and usually about 1,000 yd. from the enemy, that the full force of the attack was to be deployed, and from this position, as simultaneously as possible, it was to open the fight for fire-superiority. Then, each unit covering the advance of its neighbours, the whole line should fight its way by open force to within charging distance. If at any point a decision was not desired, it was deliberately made impossible by employing there such small forces as possessed no offensive power. Where the attack was intended to be pushed home, the infantry units employed were to act as far as possible simultaneously, resolutely and in great force. The process, and its underlying conceptions, was very similar in the British Army. It was directed to a "gradual building up of the firing line within close range of the position, followed by a final blow with the reserves in the greatest possible strength." In the

French it underwent natural modifications. It was considered (*see de Grandmaison, Dressage de l'infanterie*) that a premature and excessive deployment enervated the attack, that cover by ground should be used as long as possible to march "*en troupe*" and that a firing line should only be formed when it was impossible to progress without acting upon the enemy's means of resistance. Thereafter each unit, in such order as its chief could keep, should fight its way forward to the assault. "From the moment when a fighting unit is 'uncoupled,' its action must be ruled by two conditions, and by those only: the one material, an object to be reached; the other moral, the will to reach the object."

Problems of Defence.—To the problems of defence no army gave much attention. "The *defence*, as it used to be understood, needs no description. To-day in all armies the defence is looked upon not as a means of winning a battle, but as a means of temporizing and avoiding a decision until . . . the defending party is enabled . . . to take the offensive." "A firing line, covered and steadied by entrenchments, and restless local reserves ever on the look-out for opportunities of partial counter-strokes, are the instruments of this policy."

As regards entrenchments, in the light of what followed, and what had been foreshadowed in the Russo-Japanese War of 1904-5 (*q.v.*), there is a certain ironical interest in noting this phrase from the German infantry regulations: "The construction of trenches must never paralyse the desire for the irresistible advance, and above all must not kill the spirit of the offensive"—a sentiment echoed in the regulations of all the countries. Yet within a few weeks of the opening of the World War (*q.v.*) in 1914, the "irresistible advance" was completely paralysed—not by trenches but by the defensive power of modern firearms, especially the machine-gun. The digging of trenches, and their elaboration, was but the sequel and the supplement to this paralysing power. And the spirit of the offensive was drained with the life-blood of the warring infantries, in their futile obstinacy to recognize this transcendent fact.

Dominance of the Defensive.—In 1914, indeed, this dominance of the defensive was established in spite of the relative scarcity of machine-guns. As far back as the Egyptian campaign of 1884, Colonel Knollys, a military writer of the time, deploring that "machine-guns seem to be undervalued by the military authorities" could foresee that they were "concentrated essence of infantry." Twenty years later, in the Russo-Japanese War, the power of Hiram Maxim's invention, then a generation old, threw its ominous shadow over the battlefields of Manchuria—and movement grew stagnant. Yet in 1914 no army averaged more than two machine-guns to the infantry battalion. The legend, eagerly accepted by the French and British in excuse, of masses of German machine-guns, had no foundation in fact. The only difference was that the German machine-guns were "regimented," and this grouping contributed to their more effective handling, few as they were. The Germans believed similar legends about the British, and here the cause was largely due to the fact that the remarkably high standard of rifle-shooting, and especially of rapid fire, which had been developed with the idea of helping the attack forward, came into play most usefully as an impregnable resistance to the German attacks.

For a few weeks of war, movement was kept alive by searching for an open flank when frontal attacks proved futile. Where the frontal attacks broke down, the two sides dug in, powerless to come to grips effectively across the bullet-banned "No Man's Land." With the supplementary assistance of trenches and wire entanglements, a modicum of fire-weapons was adequate to hold such fronts, and the surplus was hurried off to the one still open flank—towards the sea.

Thus the experience of Manchurian battlefields was repeated, with emphasis. And this time, numbers were greater, distances less. The sea was soon reached, the front became static, and, with the collapse of the violent attempts to break this flankless line before it had crystallized, deadlock set in. The history of the next four years is of ceaseless renewals of the frontal onslaughts on entrenched lines held in reality by machine-guns, if nominally

by men.

New Rôle of Artillery.—Although up to the start of war, cavalry had been trained for shock action, the cavalry charge, except for one or two isolated skirmishes, became a dead letter directly the first shot was fired. Thus, infantry was compelled to assume the rôle of the decisive arm, a rôle for which its relative immobility even under bulletless conditions had never fitted it. The hollowness of this assumption was soon proved, if not openly admitted, and the decisive rôle was tacitly passed over to the artillery. The issue of any attack came to depend almost entirely on the artillery preparation, later extended by the barrage, and the infantry masses became merely the satellites of the artillery to "confirm" its success by walking forward behind the wall of bursting shells in order to occupy the shell-flattened trenches of the enemy. Thus they became once more a "residue." From mediaeval camp-followers to modern barrage-followers—the wheel had come full circle. In this rôle of occupying and clearing up—"mopping up" as it was termed—the ground conquered by the artillery, the rifle was at a discount, the man-handled machine-gun too immobile to be effective in attack, and infantry, reviving the historic grenade (*q.v.*), came to use such short-range missiles as their main weapon. The bayonet, as always in modern history, was merely a symbol in attack, although used extensively for "pig-sticking" the helpless defenders once they were overpowered. Unhappily, the military authorities still continued—as for another 12 years—to call infantry the decisive arm. Hence they continued for long to cherish the delusion of "weight of numbers" and to use infantry in masses—merely adding thereby to the weight of corpses and of the post-war pensions bill.

Failure of Mass Assault.—The lowest level of infantry tactics was probably reached in 1916, where in the Somme offensive (*see* SOMME, BATTLES OF THE) the method was for battalions to advance in four or eight waves, not more, and often less than 100 yards apart, the men in each almost shoulder to shoulder, in a symmetrical, well-dressed alignment, and taught to advance steadily upright at a slow walking pace with their rifles held aslant in front of them, bayonets upwards—so as to catch the eye of the observant enemy, an excellent imitation of Frederick's infantry *automata*, with the difference that they were no longer advancing against muskets of effective range of barely 100 yards. It was hardly remarkable that when darkness fell on the battlefield on July 1, many battalions were barely 100 strong. Later in the war the term "storm troops" came into vogue; in 1916 the term "target-troops" would have been apt. A few extracts from the pamphlet which regulated the training of the troops for the Somme offensive are worth quoting to illustrate the ideas then current. "The leading lines . . . should carry right through to the farthest limits of the objective. The assaulting troops should push forward at a steady pace in successive lines, each line adding fresh impetus to the preceding line. . . . The men in each line should be extended at two or three paces interval."

It was not inapt that the only paragraph in this pamphlet thought worthy of the emphasis of italics was that "*Finally, it must be remembered that all criticism by subordinates of their superiors, and of orders received from superior authority, will in the end recoil on the heads of the critics and undermine their authority with those below them.*"

In these long-drawn out battles, the "farthest limits of the objective" were rarely attained, though even these limits became more and more modest as the method of the "limited objective"—conquest by a progressive series of short bites which enabled the enemy to fortify fresh lines before the attack could reach open country—was substituted for the attempt at a rapid "break-through." That progress, if costly, and if made at all, was due primarily to the weight of shells poured on the defences, but also in some degree to the revolt of the soldier's natural instincts from the artificial restraints imposed by official doctrine. For when the enemy machine-guns opened, the thick and stiff waves of the "assaulting" infantry were quickly thinned, till but a remnant remained on their feet. The rest littered the ground—dead or militarily dormant. Then, human nature and primitive cunning reasserting themselves over the formalism of authorized tactics,

the more enterprising and still uncowed survivors, formed into little groups, usually under some natural leader, and worked their way, by short dashes and crawling, from shell-hole to shell-hole, "stalking" the opposing machine guns, overcoming them, and often progressing to a considerable depth with little further loss. In view of the predominant part played by the artillery, it would seem a reasonable deduction that if this limited number of infantry, trained to "stalking" instead of dressing, had been sent forward originally, they would have gained equal ground, while saving the initial 400 or 500 casualties per battalion which were uselessly sacrificed to such shibboleths as the "weight of the attack" or "the bayonet assault."

Tactics of Infiltration.—The experience of 1916 reinforcing those of 1914 and 1915 confronted military science with two alternative remedies. One was to make men bullet-proof while still capable of movement by putting them in armoured vehicles (*see* TANKS). The other, necessarily more restricted in scope because of the wide effectiveness of fire on the battlefield, was to teach men to evade bullets by "stalking"—the skilful use of cover combined with the accurate use of rifles.

While a few individual tacticians in the British Army sought to apply the "human reaction" of 1916 and fit it into an improved tactical method, the Germans were the first to incorporate it officially and practise widely these new tactics of infiltration. Based on the group instead of the line, the idea was that a widely dispersed chain of little groups should, under cover of the bombardment, probe the enemy's front to discover its weak points and thus penetrate between the posts and machine-gun nests of the defence. While the leading groups pushed onwards through the enemy's position, the "islets" of the resistance cut off from help could be outflanked and reduced by fresh troops from the reserves. Sound economy of force was embodied in the basic principle of these infiltration tactics, that reserves should be used to exploit success instead of to redeem failure—to follow and back up the leading groups wherever a penetration had been made, instead of to reinforce those parts of the front where the attackers had been held up.

In Sept. 1917 the German command employed infiltration as part of the new tactics which they tested in the "experimental" attack at Riga, on the Russian front. In November it was tried with fresh success in their counterstroke at Cambrai (*q.v.*), and in consequence became the basis of the training of their infantry for the great 1918 offensive (*see* ST. QUENTIN, BATTLE OF). Here, greatly aided by surprise, gas and fog, it achieved astonishing success, and the German troops penetrated to a depth and at a speed which eclipsed all former estimates.

By the British also the "group" idea had been accepted in the autumn of 1917, and when somewhat belatedly the training direction of the British Expeditionary Force was centralized—under an Inspector General of Training—after the early disasters of 1918, the training of the infantry was radically re-cast on more flexible lines with "soft-spot" tactics as the pivot. When the British, in conjunction with their French and American allies, retook the initiative and the offensive in the late summer, these new tactics were a contributory factor in purchasing the final victory at an economical price. In the Australians particularly, less trammelled by instinct and training than European troops, they found most able exponents. If the tanks, the lavish use of gas and smoke-shells, the flood of American reinforcements, and the decay of the German morale under the strain of its immense physical casualties, were the outstanding factors in this dramatic turning of the tide, it is unquestionable that the "soft spot" tactics saved thousands of lives in the last phase, and enabled the infantry to make better progress with lighter loss than under any previous system. Not least of its assets was that its life-saving possibilities did much to restore the moral of infantry whose confidence had been steadily undermined by years of unintelligent misuse. Its handicap was, however, that it had to be applied to and by a vast "residue" who had to absorb it under stress and without qualification, whereas it was essentially the method for

a highly trained and carefully picked élite—if its inherent advantages were to be exploited to the full.

Post-World-War Reactions.—After the war, the customary reaction took place, with even greater rapidity than after 1870. Instead of developing the lessons of 1918 and remodelling military organization in the light of this experience, all the armies of Europe reverted to 1914. Tanks, artillery and aircraft were cut down, and gas the only hope of humane warfare was forsworn; and the post-war armies were patched up again on the sand foundation of masses of infantry. So strictly did military authority adhere to 1914 that it rechristened infantry "the decisive arm," and began to train afresh for a war of mobility. No authority deemed it necessary to explain how an infantry that had so quickly become paralysed in 1914, could nevertheless become mobile when it faced machine-guns four to six times as numerous as formerly. And for each machine-gun there were added four light machine-guns, to multiply the power of fire-defence.

The sole condition which enabled infantry in the World War to make a general advance—even for a limited distance—was that hostile machine-guns be overwhelmed by artillery or tanks. With artillery the issue turned on whether the concentration was sufficiently intense so to plaster the defences with shells that their machine-guns were overwhelmed by a profusion of explosives rather than by deliberate aim. For the machine-gun was so small a target and so easily concealed, that guns rarely succeeded in hitting it except by the "plastering" method. In attacks which attained a limited success, experience showed that a concentration of one gun to every ten yards of front was the minimum necessary, while one gun to five yards became the normal standard in the sectors where a definite result was sought (*see* ARTILLERY). But with the post-war reduction of artillery, the most that the divisional artillery could provide was a very thin barrage—one gun to every 30 yards of front—on barely one-tenth of the normal frontage of a division. Even so, on the remaining nine-tenths the infantry would have to advance without support. And as the reserve of medium and heavy artillery under the control of higher formations is now of still more slender proportions, it will be obvious that infantry cannot rely on artillery to help them forward, and may have to sit passively in trenches for the first year or two of a future war, while the industries of the nation concerned are being converted to war production and the output of munitions is raised to the level of 1917. Even so, such a type of warfare is ruinous. The mere preliminary bombardment before the battle of Ypres, 1917 (*q.v.*), namely 4,283,550 shells, cost £22,000,000.

Restriction of Tank Strength.—If tanks are a cheaper and more effective means of helping infantry to advance, the possibility of this solution was practically nullified by the reduction of tank strengths which occurred in all armies after the war. For the British army retained only four tank battalions to meet the needs of 136 infantry battalions, although the former were gradually equipped with new and improved machines. The French army, more logical, retained 44 tank battalions, while reducing the infantry by 1928 to 225 battalions, but the machines were of an obsolescent wartime pattern. But apart from the questionable economy of tying modern tanks, which have become several times faster and more widely mobile than their World-War prototypes, to the service of a crawling infantry which in itself contributes little to the essential task of overcoming hostile machine-guns, there is a profounder aspect of this policy. For a survey of military history reveals that in a well-balanced army the cavalry, because of the mobility which enabled it to strike at the enemy's rear, has been the decisive arm. Its vulnerability in face of modern fire-arms brought about the decay of its former functions, and one of the outstanding lessons of the World War was the need to revive these by the substitution of an armoured mechanical cavalry. In the last few years military opinion has been gradually converted to the view that the true functions of tanks are best fulfilled by employing them as an independent arm, and constituting mobile armoured divisions to replace the cavalry divisions of former days. Progress in thought, although slow, has nevertheless outstripped progress in new equipment, and meantime armies

¹Lieut.-General Sir Ivor Maxse was the officer appointed to this post.
—Editor.

remain constituted mainly of infantry. In continental countries where conscription is still maintained, this decadent condition is almost inevitable, because all are poor, machines are dear and man-power is cheap in peace-time—if the most expensive instrument under the test of war. As regards Germany, the victorious allies were still sufficiently under the impression of war experience to impose a ban on her equipment with tanks—just as Rome, after Zama, forbade conquered Carthage to retain war-elephants.

But for wealthy industrial countries like Great Britain and the United States which have reverted to small professional armies of relatively high cost, it is not easy to understand or justify the continuance of armies which, despite their smallness, are based on a disproportionately large infantry. For the military justification of professional over conscript armies is that the former, by their high training and superior quality can gain quick results, and like Alexander's Macedonians offset opposing quantity by the swiftness and decisiveness with which they strike. History however shows that warfare has become static wherever the means of defence have acquired a material preponderance over the means of offence. It shows also that even under the most favourable conditions infantry have only a limited power of forcing a decision—because their capacity to transport weapons and to move is limited by the narrow bounds of a man's muscular strength and endurance. Infantry have been most effective when they have been a complementary arm, composed of picked and highly skilled specialists, capable of forming a pivot of combined stability and destructive power for the action of more mobile arms. Modern infantry are certainly stable, but little else. They have great defensive power, through their machine-guns, but hardly any offensive power. Always limited in strategic mobility, because of the limitations of the human legs, they have to-day lost their tactical mobility, because of the limitations of the human skin as a protection on a bullet-swept battlefield.

INFANTRY ORGANIZATION BEFORE, DURING AND SINCE THE WORLD WAR

Up to 1913 the British infantry was organized on a radically different plan from that of other armies, the battalion consisting of eight companies. Then, however, a school of reform¹ carried the day in spite of much opposition. The old "Eight Company" organisation was exchanged for that of battalions of four companies, each 200 strong. The battalion had also a machine-gun section of two guns. A company consisted of its headquarters and four platoons; a platoon of four sections. A section was commanded by a non-commissioned officer and was a normal fire unit. Four battalions, from various regiments, were grouped into a brigade. In the British Army the regiment is a unit of sentiment and the spring from which *esprit de corps* arises. It is based on a fixed regimental *dépôt* which is the common link of battalions scattered over the British Empire. The four-company battalion marked a stepping-stone in the history of the British infantry, because the platoon became the "tactical" unit instead of the company. As a logical consequence the first unit (section) decreased in size and became the command of a junior N.C.O.—a corporal or lance-corporal.

Other Armies, 1914.—In the German, French and U.S. armies the regiment consisted of three battalions, and was a tactical as well as an administrative unit. In Germany it was commanded by a colonel with a lieutenant-colonel as his second-in-command. The battalion commanded by a major was divided into four companies, each commanded by a captain. The company was divided into three sections (*Züge*), each under a subaltern. Every infantry regiment and Jäger battalion was provided with a machine-gun company of six guns, plus one spare.

The French company was organized into four sections, commanded in war by three subalterns and one adjutant (superior company sergeant-major). The sections were grouped in pairs to constitute *pelotons* (platoons) under the senior of the two section leaders. Machine-gun sections were allotted to battalions as in the British Army. In the United States the company was

¹Lieut.-General Sir Ivor (then Brigadier-General F. I.) Maxse was the chief advocate and pioneer of this reform.—Editor.

composed of three officers and 150 rifles, divided into two sections, each of three squads. In the World War, however, the U.S. infantry regiment was remodelled on the continental model, having also a regimental machine-gun company, a headquarters company and a supply company.

Thus before the war the infantry battalion consisted in almost every country of about 1,000 men and was divided into four companies each commanded by a mounted officer. But the British battalion was the weakest in fighting strength, because its First Line Transport and other services were deducted from its 1,000 rifles, whereas the regimental systems of continental infantry provided these services from a separate establishment. The subalterns were dismounted officers whose commands varied as follows: British 50 men, German 80 men, French 50 men, United States 75 men. But in the British infantry a large proportion of the 50 men borne on the strength of the platoons were absent on other duties. They were signallers, machine-gunners, bandmen, transport drivers or pioneers—and were in fact everything except fighting infantrymen, and they should never have been on the rolls of the fighting platoons. The British Treasury, however, ordained otherwise and thus made training and fighting difficult for every platoon commander.

Changes During 1914-18.—During the progress of the war the basic organization of the infantry of the belligerent powers was not materially altered. The changes were chiefly in the direction of additional weapons and a multiplication of kit, which reduced the infantry soldier to a beast of burden laden under a weight which destroyed his mobility. In 1915 the British infantry as compared with the German suffered from a paucity of machine-guns and was slow to make good this defect. At first an increase was made (up to four per battalion), and when manufacturers raised their output these were formed into machine-gun companies. They were gradually divorced from the infantry and formed into a machine-gun corps, firstly as brigade machine-gun companies and finally as divisional battalions. By the time this had been accomplished the lighter Lewis gun had made its appearance and had been allotted to infantry units. The first issue (not long before the battle of Loos, 1915) was only four guns per battalion.

The tendency at first was to use this weapon like a heavy machine-gun, but when its characteristics were better understood it took its place as a company weapon in 1916, and as a platoon weapon in Feb. 1917. By March 1918, two sections of the four in the platoon were armed with one Lewis gun each. The allotment of an automatic weapon on such a scale marked an important step in the tactics of infantry. One of these new weapons handled by only two men could deliver a stream of bullets equal to what could formerly be projected by 25 soldiers with rifles. This led to a reduction in the strength of the section—to one leader and six men. Thus the British subaltern officer's command in battle became 28 fighting men, as compared with 50 in 1914—but the Lewis guns increased the fire-power of the platoon out of all proportion to the number of its men and had also increased the load they carried.

The Germans were faced with the man-power problem before any of the other belligerents, and they also appreciated the value of the light machine-gun. In March 1917 they issued three to every company and afterwards raised this allotment to six by giving two guns to each platoon. Finally each German battalion consisted of a heavy machine-gun company of 12 guns and three infantry companies armed with six light machine-guns each, without counting the special machine-gun companies allotted to divisions for every battle. This tremendous increase in automatic weapons had an inevitable effect on infantry formations. The costly attacks on narrow frontages were abandoned. The successive lines or waves of men gave place to open formations. The four sections of a platoon were gradually separated from one another and compelled to manoeuvre and fight under their own leaders. The frontages allotted to the leading platoons were increased, and in 1918 we find platoons attacking on frontages of 200-300 yd. with very small effectives. Fire-power was at last beginning to be understood.

Special Weapons.—In addition to the Lewis gun, rifle-grenade and hand-grenade the Stokes light mortar proved to be a useful infantry weapon. Although it did not form an integral part of battalion equipment, the brigade light-mortar batteries drew their personnel from the infantry and the mortars were allotted to battalions during operations. The light mortar was the nearest approach to an infantry gun in the British Army and though not an ideal weapon rendered great help in reducing enemy machine guns and strong points. The German mortars in the summer of 1918 were distributed as follows: each regiment had a regimental "*minenwerfer*" company, organized in three sections, each with three light *minenwerfer*, and in addition two or three medium *minenwerfer*.

Post-War Organization.—The British infantry battalion was first reorganized on a basis of a battalion headquarters wing, which included a machine-gun platoon of eight guns, and four companies. Each company consisted of company headquarters and four platoons, each platoon of headquarters and four sections, two of which were armed with one Lewis gun each. In 1928, however, the British organization came into line with foreign armies, and to a slightly fuller recognition of the power of machine-guns, by replacing one of the four companies with a machine-gun company of 12 and ultimately 16 guns. The light mortar has been abandoned as too immobile. The Lewis gun is also considered too heavy and its replacement by the Browning is under consideration. In order to increase the manoeuvring power of the platoon various experiments have been tried, such as concentrating the Lewis guns of the company into one platoon and leaving the others as rifle platoons.

The French battalion comprises a headquarters group, three ordinary companies, a machine-gun company and a section of accompanying weapons (mortar or infantry gun). The company at war strength is composed of a headquarters section and four combat sections, and the section of three groups. The fighting group consisted at first of a team of riflemen and a team of automatic riflemen, each team comprising a corporal and five men. These teams (*équipes*) have now been merged in the group. In peace or when the strength is lowered by casualties the number of sections in the company or groups in the section may be reduced, but the actual groups are maintained at full strength. The French place their reliance upon the light automatic rather than on the rifle, and their new organization is the outcome. Although their group is stronger than the British section, to which it corresponds, the effort of all its ten men centres round the service and protection of the one *fusil-mitrailleur*, and the riflemen inevitably lose much of the value of their greater mobility. On the other hand the British organization though possessing somewhat greater freedom and power of manoeuvre, means that the platoon commander has the difficult rôle of combining four sections of which two are radically dissimilar in arms and in action to the other two. The German battalion also consists of three companies and a machine-gun company. A company is organized in three sections; each section (*Zug*) is divided into four or five groups (*Gruppe*) of eight men each—two light machine groups and either two or three rifle groups.

THE FUTURE OF INFANTRY

If we recognize as we must that infantry as constituted and trained to-day can make no headway against machine-guns in normal open country, where will be their place on a future battlefield? Should we be content to regard them merely as a human reservoir for supplying machine-gunners to the ranks of a defensive position and the tanks of a mobile force; or, for filling up conquered territory with a flood of military "police"? Even these two "residuary" rôles may be restricted. For military opinion is gradually coming to realize that it is not economy of force to employ six vulnerable men to man-handle one machine-gun in action when, if placed in a light tank, two men can bring it into action and out, switch it quickly to any required sector and maintain fire while in movement—thus, in Napoleon's phrase, multiplying "force by velocity." And although even advanced military opinion still believes that a crowd of infantry are necessary to play the "walking on" part of occupying conquered territory, it

is a reasonable suggestion that this might be controlled as effectively and with less provocation, to the inhabitants—by a sprinkling of engineers protected by tanks and aircraft, sitting at the sources of light, heat, power and water supplies. Moreover, unless this vast "residue" is to wait at home until the war is won, they will be moved forward very slowly on their feet. If there is one feature of past wars which air power, even uncombined with gas, has relegated to the lumber room of history, it is that of sluggish marching columns on roads. It is not necessary to assert that they would be destroyed; mere alarms and consequent dispersal might prevent them reaching enemy territory or any battlefield until the enemy's defeat had been accomplished by more mobile instruments.

For all these reasons the conversion of the residuary bulk of the infantry to more effective service—or, in the case of conscript armies, to work in which they can swell the production of wealth in peace and munitions in wars—is indicated. The process will doubtless be slow so long as the public are content to pay high premiums for inadequate military insurance, and military authorities remain slow to shed old habits—whether of spending thought, spending lives or spending money.

There is however scope for a revived light infantry—a highly trained corps d'élite of small numbers compared with present standards. For although the decisive struggles of history have normally been fought in the plains, theatres of minor war include mountainous, wooded or otherwise difficult country where the man on foot—because of his unique locomobility—must still play an important, even the most important part. Again, while the use of infantry to attack in typically bare or rolling country, such as the greater part of Europe, is merely a homicidal enterprise, these commonly contain areas where fighting men on foot are useful, if not essential. Such areas include woods, broken ground, villages or defiles obstructed by natural or artificial obstacles. Here tanks, even the diminutive machines now being produced, may not be able to pass, and gunfire from a distance may prove ineffective.

Thus we see that as tanks were aptly called landships, so the infantry of the future will be land-marines—to act as the landing parties of the armoured "land-fleet" of to-morrow. For such a complementary rôle only a small portion of the infantry strength of to-day would be necessary, and this reduction might be made to enhance their effectiveness, directly and indirectly; directly, by renewing their pride of "arm" through allotting them a specialized, instead of a "general" rôle, and by diminishing their "superfluous" casualties through a real dispersion of the target which they offer. After the war, the new tactics of infiltration and manoeuvre were incorporated in the recast infantry doctrine but, in the tedious process of winning theoretical acceptance, their practical application was whittled away. How can the thousand men of an infantry battalion find room and cover to infiltrate and manoeuvre on a frontage of 800 yards or less, which is all the French doctrine accords, or even on a frontage of 1,000 yards, as is laid down as normal in the British manual? Such conceptions may be heading for another and more fatal Somme.

Indirectly, a reduction in numbers would contribute to mobility. For while no army could hope to provide sufficient mechanized transport for its present numbers of infantry, future "land-marines" might be carried in the vehicles of a mobile armoured force. Just as mounted infantry (*q.v.*) were trained to ride on horseback as well as to fight on foot, so, in this motoring age, there is no reason why men should not be trained both to drive a fighting vehicle and to act on foot as skirmishers, dismounting from their vehicles. With smaller numbers, too, pay can be higher and a higher standard of selection enforced. For in a professional army man-power and its upkeep is the dearest item. Similarly, when infantry work of wider scope and at greater range is needed, an armoured force might be accompanied by armoured infantry carriers. Even in this case we should fulfil the law of economy of force if such infantry were also qualified to form spare crews for fighting vehicles. What infantry might lose in numbers they would gain in status; the mockery of calling them "the decisive arm" will be no compensation for treating them as mere barrage-followers; but to be the picked light infantry of a mechanized army

would constitute a greater distinction than being called the cannon-fodder mass of past wars.

The Training of Infantry.—How should the training of infantry be developed in order to fit them for a new effective rôle? The answer is simpler, though more difficult of execution, than it seems. For the right training was foreshadowed in the methods devised in 1918. Unhappily, instead of being developed, they have been allowed to lapse. No greater error is current to-day than that infantry is the most easily trained arm, for none needs more care, more skill if it is adequately to play its part. And the reason why it is a difficult arm to train is because it possesses so few concrete elements. It is concerned with tactics and ground.

To train infantry to be tactically minded is to exercise an art, whereas to train gunners is to apply a science; the one requires an artist the other a calculator. The man in the ranks of the artillery, the tank corps, the air service, is often a mechanic—executing a concrete task in a definite manner. Initiative is the province of the officer, but even he in the subordinate ranks of other arms is largely concerned with producing a material effect. But the infantryman's use of material—his weapons—is only complementary to the use he makes of tactics and ground before he gets to grips with his enemy. Because of the variety of elements with which he has to deal, the infantry commander is apt to confine himself to such parts of the subject as he himself knows best. Hence a tendency to over-emphasize such matters as drill, musketry, bayonet fighting, which can be easily mastered by the intellect of the average officer. Hence also the neglect of tactical training, which demands thought and is difficult to learn and teach because it deals with moral and variable factors and requires a modicum of imagination.

The right tactics of infantry must be based on nature and human nature, not on mechanics or geometrical perfection. Yet it is almost incredible how in the past showy evolutions deduced from the parade-ground have persisted on the battle-field. The future infantry must be permeated by the best doctrine which the war can teach, and this doctrine must be expressed in language so simple and by metaphors and illustration so clear, that it can be as readily grasped by subalterns and corporals as by general officers. Its manual of instructions should be as intelligible to the Australian bushman as it is to the staff college graduate.

In 1806-15 the British were capable of a sustained effort in the theory of tactics as originated by Sir John Moore, and there is no reason why infantry should not to-day be trained to as high a pitch of comparative excellence. These tactics would be based on the little group of men following a corporal whom it knows because he has trained it. In the hurly-burly of modern war these little groups retain cohesion because men will follow a leader whom they see close to them, whose voice they can hear and whose presence is familiar. These groups will act by infiltration and manoeuvre, not fearing the isolation due to a wide dispersion of the groups, because they know that in dispersion lies safety, and because the comradeship within the group is a more real support than that of a continuous line, wherein each man felt himself a single peg in a long row.

For decades the infantries of all countries attempted to produce tactics suitable to new weapons and conditions of war, by multiplying the lines which were successfully used by their fore-runners in the days of the musket—with its short-range and slow rate of fire—and of the case shot and solid shot of the artillery. They moved shoulder to shoulder with intervals. The idea of manoeuvre was absent. Even down to the closing stages of the World War the action of infantry units in battle—as distinct from a skirmish or an affair of outposts—was confined to frontal attacks. Manoeuvre was the weapon of the higher commanders only.

In any large action each of the infantry units was allotted only a fraction of the frontage of the force of which it formed a part. This narrow sector was hedged in on either side by neighbouring units of a corresponding size. How then was it possible for attack or defence on the part of infantry units to be aught but straight to their front? How can they manoeuvre if they have no space to move in? And how can they be expected to move to a

flank if they possess no intervals and no flanks? The opportunity came when the range and deadliness of modern weapons began to enforce dispersion. But instead of exploiting it, military orthodoxy has rather sought to restrict it—as a deplorable evil—and clings to pre-war methods.

Before the World War lines of infantry in extended order made rushes and utilized ground; they fired in small bodies and opened at long ranges; at the decisive points they were gradually thickened up into a crowd. These crowds surged forward at a given signal and assaulted to their front. But the infantry soldier was so near his neighbour in these sham battles that he had scarcely sufficient space to load and fire his rifle without hitting one of his friends; the units became so mixed together in the process of thickening up that neither the corporal nor the subaltern could exercise control over his own men or any unit; often he could not find them during the decisive stage of the battle. Fortunately the "cease fire" sounded and re-organization took place; but in 1914-18 there was no "cease fire" and no umpires and the warring infantries were slow to learn. This was no doubt inevitable, and is a sufficient reason to try now to gather the lessons of 1918, but it must be remarked regretfully that the tactical experiences of 1918 have not been embodied in the tactical handling of units in 1928. Official manuals seem always to lag behind their own age, and in fact human nature did conquer the old line formation before the groups were officially sanctioned. The evolution was the more natural because the real opponent—the machine-gun—was also a firing "point" rather than a firing "line." These two factors, combined with the general dispersion of troops on the battlefield, served to bring about the articulation of infantry into independently moving "points" each and all capable of manoeuvre. This therefore should be the keynote of future infantry tactics. Infantry must only be used for attack in country which gives them adequate natural cover for infiltration and manoeuvre. They must be given frontages wide enough for them to find and use cover, and to ensure that their approach is more or less unsuspected. They must avoid stereotyped methods of movement. They must probably revert to individual weapons.

The only infantryman of use in modern warfare is one so highly trained in the use of cover that he can stalk machine-guns, and so highly trained as a shot that he can pick off their crews at close ranges. For volume of fire infantry cannot compete with mechanized arms—it is an arresting comparison that even the small and immature Armoured Force formed in 1927, which included but one battalion of tanks, had a greater "fire-pumping" capacity than a whole infantry division had previously. Extreme accuracy of fire is the only justification for the infantryman. In his training, too, the old instinct of alignment must be eradicated and replaced by a sense of direction. This is all the more important because the World War introduced a new element—smoke (*q.v.*). Mist or fog has often been a decisive but accidental factor in battle, but with the introduction of artificial fog which can be projected at the will of the user, the enemy's view is impeded while his own movements take place in daylight until he reaches close quarters. Thus smoke is an invaluable aid to infiltration, and although, like most other inventions it has been much neglected since 1918, it will be indispensable to the infantry of the future. Whereas the slender artillery of to-day can give the infantry no adequate barrage, it could provide an effective blanket of smoke with the same quantity of shells. Lastly, if infantry is to possess an adequate agility its weapons and equipment must be lightened. In fact the infantryman of the future must be equipped as an athlete.

The Control of Infantry.—Do these individualistic infiltration tactics involve a complete abandonment of control? By no means. The group itself was a step towards the restoration of control if only in the lowest grade. Reformed and modernized drill could be the means whereby the scale might be raised. In recent generations we have seen that armies retain drill movements for the parade-ground and throw them aside when they go on active service. As human nature in battle retains its instinctive habits it is scarcely surprising that in moments of crisis one has seen men advancing, against the deadly fire of machine-guns,

in close-packed bodies. But if drill were brought up to date on the lines of dispersed order and the group, it would constitute an ingrained method of control that could be used to quicken the manoeuvre of deployed units and direct them to take advantage of local situations. Voice control would be out of the question, but so long as signals were few and simple, visual control could be used particularly if a clearer means of signalling were devised.

Let anyone with experience of war ask himself if there were not moments in his recollection when he might, had his men been drilled in such a system, have saved precious minutes, an opportunity which never returned, by the use of a signal instead of the slow method of sending a message by runner. The old close order was under control but modern fire has made it impossible. With extended order the battle developed into the chaotic movements of an uncontrolled mob at the decisive point. An ingrained system of battle drill might enable a unit when deployed into its fractional parts, to be manoeuvred, to be opened or closed in "concertina" fashion according to the ground and local circumstances. Such a system was embodied in the post-war training manuals. But it was made an addition to instead of a substitute for the existing close order drill. Hence the claims of parade-ground ceremonial, always dominant in practice, have restricted its application. Thus we solemnly inculcate on the parade-ground a set of evolutions which date from the Crimean battlefields, but to-day bear no relation to tactics—as they were first meant to. (See SMALL ARMS; CAVALRY; TANKS; also STRATEGY; TACTICS; WAR.) (F. I. M.; B. H. L. H.)

INFANT SCHOOLS. The provision in modern times of systematised training for children of pre-school age may be dated from the village school at Waldbach founded by Jean Frédéric Oberlin in 1774. Robert Owen started an infant school at New Lanark in 1800. Further impetus and a new direction were given to the movement by Friedrich W. A. Froebel, the creator of the kindergarten (*q.v.*), where play, nature-study, and handwork are directed to the development of the child's latent powers. Dr. Maria Montessori (*q.v.*) marks an epoch in infant training. Her experiments with mentally defective children showed her the educative value of sense and muscle training, and she devised an elaborate set of educative toys by which the children learn to observe sounds and forms and colours, numbers and size. Each child chooses his own activities and puzzles out problems as they present themselves to his own mind; there is a minimum of active intervention by the teacher, though her skill in quiet guidance is the key to the whole. Dr. Montessori's sensory training does actually lead to the beginnings of reading, writing and numbers. She precludes all learning by rote at this early stage, and so all recitation. The training of the social sense is secured by common domestic tasks, care of gardens and of pets. The genius of Rachel and Margaret McMillan and Grace Owen has created a type of school (see NURSERY SCHOOLS) which aims at providing the children of poor and crowded districts with something approaching the ideal nursery of their more fortunate fellows—fresh air, wholesome food and happy activity, with sleep at proper intervals.

United Kingdom.—Up to 1905 it was the general English practice since the Education Act of 1870 for education authorities to provide facilities for teaching children between three and five where the parents desired it. In 1905 Article 53 of the Code empowered them to refuse admission to children under five. In

1907 the Consultative committee of the Board of Education called attention to the gap between the care and advice given at baby clinics and the medical inspection at primary schools, and recommended the establishment of nursery schools to bridge this gap. The Education Act of 1918 empowered education authorities to supply or aid the supply of schools for children from the age of two "whose attendance at such a school is necessary or desirable for their health, physical or mental development." The 1923 act in Northern Ireland contained a similar provision. But the Prefatory Memorandum to the 1918 act deprecates the creation of a separate caste of nursery school teachers. In 1923 the Joint Parliamentary Advisory committee reported on the success of these schools, but added that "the cost *per capita* offers a serious bar to their extension." Sir George Newman, however, in his *Annual Reports* as Medical Officer to the Board of Education, repeatedly urges their value to health and pleads that a stitch in time saves nine. He urges that they might be amalgamated with the day nurseries where children whose mothers are out at work are cared for all day from the age of nine months. On March 31, 1926, there were 27 recognised nursery schools, 12 under local authorities and 15 maintained by voluntary effort.

The *Handbook of Suggestions for the Consideration of Teachers* (Board of Education, 1927) distinguishes the nursery stage (from 3 to 5) from the infant stage (from 5 to 8). In the nursery stage there are to be no formal lessons in reading, writing and arithmetic; the children are to form wholesome bodily habits, to sleep and play in the open air, and there is to be motor and sensory training. In the infant stage reading, writing and arithmetic are not to be forced, but may be begun. There is to be "direct contact with things as a means of learning." The actual practice in infant schools differs widely from the rigid formalism of the more old-fashioned schools to the freest use of individual methods.

Number of Pupils, 1924-5

Age	Boys		Girls		Total	
	England	Wales	England	Wales	England	Wales
3-4 . .	20,441	1,929	18,574	1,879	39,015	3,808

Other European Countries.—In Austria under the act of 1872 kindergartens were recognized as part of the public educational system. In 1879 the State established a kindergarten practising school. From 1889 Vienna began to establish municipal kindergartens. Since 1918 the city has rapidly developed *Volks-kindergärten*, where working-class parents may leave children between two and six from 7 A.M. to 6 P.M. There are also *Normal-kindergärten* with shorter hours. Nominal fees are charged, besides a small sum for breakfast and dinner in the *Volkskindergärten*, but these may be remitted or reduced. Montessori and Froebelian methods are combined except in one purely Montessori experimental school. There is frequent medical examination.

In Belgium, for children between three and six education is provided in the *écoles gardiennes*. They are free but not compulsory, are provided by the communes, receive a State grant, and are under government inspection. Private schools must conform to the conditions of the communal schools. The State first recognized these schools in 1833. In June, 1927, the Ministry issued a new set of model regulations, which the communes are free to adopt or modify. Froebelian and Montessori occupations are recommended. Reading, writing and arithmetic are excluded. No time is allowed for sleep. In all schools there is a *femme de service* to see to the cleanliness of the children and to their physical needs.

In France, the first regular infant school was established in Paris at the beginning of the 19th century. In 1828 a model school was started, followed shortly by similar institutions all over France. State recognition and inspection were granted. In 1848

the name *école maternelle*, which these schools have since borne, was given to them. Every commune must have one of these schools or a *classe enfantine*, which has now become simply an *école maternelle* attached to a primary school. Admission is free, but not compulsory, for children between two and six. New regulations were issued in 1921 and 1927. Reading, writing and arithmetic are taught to the older children. Classes are to be from 25 to 50 in size. All schools must have a *femme de service*.

Kindergartens and day nurseries (*Kleinkinderbewahranstalten*) for children under six in Germany are maintained voluntarily by local authorities and also by religious and charitable bodies, but they are subject to State inspection. Fees, if charged at all, are very low. In addition there are private kindergartens and day nurseries supported by the parents' fees. Froebelian methods are general, but a decree of the Prussian Ministry of Education (1920) makes the study of Montessori methods compulsory in recognized training courses for kindergarten teachers. There are few purely Montessori schools. The age of compulsory attendance is six.

Under the Act of 1891 in Hungary, kindergartens (in the larger communes) and day nurseries are established in addition to what is done by voluntary effort.

The first efforts to provide infant care and training in Italy were made by Ferrante Aporti, who established *asili infantili* early in the 19th century, and whose ideas in many ways resembled Froebel's. In 1907 Dr. Montessori opened a *casa dei bambini* in a tenement house, where she applied to normal infants the ideas formed by her experience in training mental defectives. In the year 1921-22 there were 5,902 *asili infantili* attended by children between three and six, including kindergartens, *casa dei bambini*, and *sale di custodia* (day nurseries), some communal, some private. Some are free, whilst others charge fees. The decree of December, 1923, authorises the establishment of *scuole materne* by voluntary effort in collaboration with the Ministry; also of training colleges for teachers in these schools; and allocates an annual State grant of five million lire.

Pre-school training has so frequently been the outcome of an attempt to cope with the evil effects of industrialism and overcrowding that it is not surprising to find it less developed in Scandinavia than in more highly industrialized countries. Norway has day nurseries and kindergartens in Oslo, both communal and private. A few Montessori trained teachers are at work in and near Oslo. Denmark has Froebelian "public gardens" in Copenhagen for children from three to six; the mothers are allowed to come also and bring their sewing. In Sweden the primary schools have infant departments for children between six and eight, but education is not compulsory before the age of seven.

In Switzerland each canton controls its own schools. Generally speaking the larger towns in German Switzerland have communal kindergartens and the smaller ones day nurseries, maintained by voluntary effort with a communal grant. In French Switzerland the *écoles enfantines* form the lowest division of the primary school under cantonal authority, and there is a more formal syllabus, though Froebelian methods are also practised. (See also KINDERGARTEN, MONTESSORI, MONTESSORI SYSTEM, NURSERY SCHOOLS and their bibliographies.)

INFERENCE: see LOGIC.

INFERIORITY COMPLEX, a psychoanalytical term, signifying a complex, or pattern of emotionally toned ideas concerning what the subject feels to be his own inferiority. The inferiority may actually exist, or it may be imaginary. The emotions attaching to the ideas of inferiority are supposed to cause the subject to attempt to compensate for his inferiority in various unnecessary ways, such as causeless pugnacity, unprovoked attacks on others, or anti-social behaviour. The general concept

is widely used but with little exactitude of definition, different writers referring to widely different types of feeling and behaviour under this term.

See A. Adler, *The Practice and Theory of Individual Psychology*.

INFINITE, a term used in mathematics, philosophy and theology with various meanings which are apt to cross each other and cause confusion. It is not possible to do more here than indicate the chief notions associated with the term.

Negative and Positive.—Speaking broadly, one may distinguish between the negative meanings of the term and its positive meanings, and also between its use in connection with what is quantitative, and its use in connection with what is not quantitative, but only qualitative. The negative meanings of the term may be expressed variously (according to context) by "indeterminate or endless in quantity or extent," etc., and "indefinite or indeterminate in quality."

The positive meanings may be expressed by the expressions "self-determined," "self-dependent," "complete" or "perfect," as the case may be. The negative use of the term is no doubt the older; it is the one most obviously suggested by the form and the etymology of the term (Latin *in*, "not," and *finis*, "end" or "limit"). The positive meanings were evolved later as the result of philosophical and mathematical reflection on the kind of objects commonly described as infinite. Such reflections have also led to the introduction of numerous distinctions among "infinities," such as "internal" and "external" infinities, "finite" and "infinite" infinities, "absolute" infinite and infinite "of its kind," "single," "double" and "treble," etc., infinite, and, of course, the infinitely great and the infinitely small (or "infinitesimal"). To explain all these distinctions adequately would take up too much space, but the main points should become clear from what follows.

The Infinite and God.—In the history of Western philosophy the term "infinite" (*τὸ ἄπειρον*) is met with, apparently for the first time, in the teaching of Anaximander (6th cent. B.C.). He used it to describe what he conceived to be the primal matter, "principle," or origin of all things. His teacher Thales had suggested that it was water; later thinkers identified it with air or fire, etc. What Anaximander probably meant to suggest was that the primal substance must have been something indeterminate or indefinite in quality as compared with such qualitatively definite substances as water, air, fire, etc., which emerged from it in course of time. Whether he conceived his primal substance as indeterminate in quantity as well as in quality is not certain, though highly probable.

At all events the notion of things indeterminate in quantity, or "without end," must have become familiar fairly early, especially in connection with ideas about space, time, number, and the existence and powers of God. Space, even perceived space, seems in a sense to have no boundaries—it seems to fade into a larger space beyond, and the space beyond can only be imagined or conceived as surrounded by more space, and so on indefinitely. Time too seems to have no limits—whatever the period of time or duration that we live through or imagine or conceive, it is always possible, indeed necessary, to supplement it with more time "before and after." The series of numerals likewise is endless—by adding and subtracting one can extend it both ends indefinitely. Similarly with ideas about God. Once the stage of limited, local deities was passed, God was gradually conceived to be unlimited in power, of infinite duration, and holding sway over endless space. Curiously enough it was not until recent times that there has been a return to some extent to the conception of a Deity of limited power. Deeply impressed with the reality of evil and suffering in the world, some thinkers have found themselves in the dilemma of having to choose between the infinite goodness and the infinite power of God; and they preferred to abandon the belief in His omnipotence. Whether the dilemma is valid, is a question that need not be discussed here. Some find no serious difficulty in reconciling the apparently conflicting alternatives, when due allowance is made for the implications of human free-will.

The Infinite and Vastness.—Intimately connected with the earlier conception of the infinite, especially in its application to

space and time, was the idea of immensity or vastness. This was a perfectly natural combination or fusion of ideas, which still clings to the popular use of the term infinite. In a sense the dissociation between "infinite" and "vast" was begun fairly early. Zeno's paradox that motion is impossible, because the moving body would have to pass through an infinite multiplicity of points or positions in order to reach even a near destination, obviously implies or even asserts that a finite line or distance contains something infinite, namely, an infinite multitude of points or positions. So that in some way a short finite distance having definite, known limits may still in some way be infinite, that is infinite internally (*i.e.*, infinitely divisible), though not externally (because its limits are fixed).

But the paradoxical method of Zeno failed on the whole to bring out the element of truth in his teaching. And the lesson had to be repeated by Spinoza, among others. His favourite illustration of the internal, finite infinite (or the infinite within a finite whole) is that of a small circle containing a still smaller circle with which it is not concentric. The space between the two circumferences is finite and small. The minimum distance and the maximum distance between them is known. Yet within this small finite space, and within the limits marked by the minimum and the maximum distance there is an infinite variety of distances between the two circumferences. The space is externally finite, internally infinite. So that the infinite is not necessarily "vast" (hence the poet's note about holding infinity in the palm of the hand), nor does it depend on the absence of "limits."

Infinity a Quality.—Infinity is rather some kind of positive character or quality. What this quality or character is, Spinoza does not make quite clear except in the case of the "absolutely infinite" and the "infinite of its kind." But what he says in this case is very suggestive, and rather like more recent conceptions of the "infinite" as formulated by Dedekind and various contemporary mathematicians. By "the absolutely infinite" Spinoza meant God as the perfect, complete, self-dependent, self-determined ground of all that is. Extension and Thought, which are "attributes" (that is, aspects of God or the Universe) are each "infinite of its kind," that is, each complete in its nature, but not, of course, the whole of Nature (or God). Finite things (or finite modes), on the other hand, are characterized by fragmentariness, incompleteness, dependence on other things outside themselves, though they are all ultimately parts of the infinite.

Now, this conception of the "infinite" is, from the standpoint of philosophy at all events, the most interesting and essential feature in the newer mathematical conception just referred to. This feature may be stated in the following quotation from A. E. Taylor's *Elements of Metaphysics* (Book II., Ch. iii.):—"The infinite must not be confounded with the indefinite or unfinished. Its fundamental property is not the merely negative one of having no end or 'last term,' but the positive one of having an internal structure which is the harmonious and complete expression of a single self-consistent principle. The finite, again, is finite not primarily merely because it has a 'last term,' *i.e.*, because there is something else outside it, but because its 'last term' is arbitrarily determined, *i.e.*, determined by something other than the principle of its internal structure. In other words, the essential defect of the finite is that it is not solely determined by its own structural principle. We can see this even in the simple case of the familiar 'infinite series' of arithmetic and algebra. Such a series as $1, \frac{1}{2}, \frac{1}{4}, \dots$ is 'infinite' not merely because you never come to the last term, but because its character is determined from within, solely by the principle according to which each term is derived from the one before it; that the series has no end is a simple consequence of this positive property of self-determination. But suppose I take n terms of this series and no more, where n is a specified number, the resulting series is now *finite*, not primarily because there are more terms of the same kind outside it, but because the number of terms to be taken is not prescribed by the law of formation of the series, but fixed with reference to some object independent of the principle of the series itself. In other words, only the infinite is in the full sense of the words a completely self-determined whole. The finite is the imperfect, not

primarily because there is something outside it, but because its contents are not solely prescribed by the principle of structure which they embody."

For the special uses of the notions "infinite" and "infinitesimal" see articles SERIES, FUNCTION, GEOMETRY and CALCULUS, *Infinitesimal*.

INFINITIVE, a form of the verb, properly a verbal noun, but usually taken as a mood. (See GRAMMAR.) Latin grammarians gave it the name of *infinitus* or *infinitivus modus*, as not having definite persons or numbers. The infinitive form of the English verb consists of the preposition "to" coupled directly with the unaltered verb root as in "to see." When a word is inserted between the preposition and the verb the result is called a "split infinitive," as "to clearly see," "to freely give," etc.; this form is a bugbear of the strict grammarian.

INFINITY, a term employed in common usage for anything of vast size, but strictly applicable only with the implication of the immeasurably or innumerable great, or of the impossibility of being measured or counted. In the strict sense the term is employed in metaphysics and theology and mathematics. The term is from the Latin *in* (not) and *finis* (end) and thus has the etymological significance of "endless."

The unlimited straight line has length without limit; it cannot be measured off by the repeated application of any unit; it transcends all possibility of measurement, and in this sense it is said to be infinite. A line is also infinite as regards the number of points on it; between any two points on a line there is another, and indeed an infinitude of others; on any line segment there is a smaller line segment, and hence an infinitude of line segments such that each of the segments after the first is included in each of those which precede it. Thus a line exhibits both infinitude of measurement and infinitude of subdivision. Space likewise is infinite in extent and it possesses an infinitude of points, of lines, of planes and of bounded portions of space. Endlessness as regards extent or distance and endlessness as regards subdivision are characteristics of space by which it is seen under the aspect of the infinite. There is a shorter distance than any which we have measured and a longer than any which we can conceive. But boundlessness or endlessness is not equivalent to infinitude. A confusion of the two notions was current in antiquity and has appeared also among modern thinkers, as Hobbes, and Hegel, for instance. A circle, considered in the modern aspect of line is endless, but we would not apply to it the concept of infinitude as regards measurement, though as regards subdivision it exhibits the characteristic quality of infinitude. Space is endless and infinite, the circumference of a circle is endless but finite as regards extent.

The Infinite in Metaphysics and Theology.—Tracing history back to the earliest possible date, we are forced to postulate an earlier period still and then one preceding that, and so on without end. Looking forward we conceive vast stretches of the future; and beyond any time of which we can think we are forced to postulate a still later time to come. Distances on the earth are small compared with the distance to the sun, and that itself is small compared with the distances of some of the stars; and beyond the furthest reaches of our telescopes we imagine still unending stretches of space. We have never seen a thing so small that we cannot imagine a smaller, or measured a thing so great that we cannot conceive a greater. But we have never experienced the infinitely small or the infinitely great, though we have formed a notion of them. Infinity is a mental concept. In early Greek philosophy (see IONIAN SCHOOL OF PHILOSOPHY) it appeared under the aspect of the boundless ($\tau\omicron\ \alpha\pi\epsilon\iota\rho\omicron\nu$), and as such it was discussed at great length by both Plato and Aristotle. They gave much thought to the question as to which is the more truly

real, the finite objects of sense or the universal idea of each thing laid up in the mind of God. They enquired concerning the nature of that unity which underlies the multiplicity of perceived objects; and the same problem, in various forms, has engaged the attention of philosophers throughout the ages.

In Christian theology God is conceived as infinite in power and knowledge and justice and goodness, uncreated and immortal. In some oriental systems, absorption in the infinite is the highest end of man, his perfection resting in the breaking down of human limitations.

The metaphysical and theological conception of the infinite is open to the objection that a finite mind cannot form an adequate or appropriate conception of such an object of thought and therefore cannot form trustworthy judgments concerning it; and the matter has been extensively debated. Sir William Hamilton's philosophy of the "unconditioned" and Herbert Spencer's doctrine of the infinite "unknowable" give evidence of this controversy. (See the articles on the thinkers mentioned, and also those on DESCARTES, MALEBRANCHE, SPINOZA and ZENO.)

The Mathematical Infinite.—If the law of variation of a magnitude x is such that x becomes and remains greater than any pre-assigned magnitude however large, then x is said to become infinite, and this conception of infinity is denoted by ∞ . If the law of variation of a magnitude x is such that x becomes and remains less than any pre-assigned magnitude, however small, then x is called an infinitesimal and is said to approach the limit zero. These conceptions of the infinite and the infinitesimal are analogous to the metaphysical infinities of measurement and of subdivision; but they differ from the latter in a marked way in that the mathematical concepts are defined entirely in terms of that which is finite. The absolutely infinite is in no sense involved. What is described in each case is a type of variation. These conceptions are intimately involved in the articles: FUNCTION, LIMIT, SERIES, NUMBER SEQUENCES, and CALCULUS.

Through the doctrine of geometrical continuity (*q.v.*) and the application of algebra to geometry arose the important notion of infinity as a localized space-conception, so that mathematicians come to speak of points at infinity, lines at infinity, and planes at infinity. It is said, for instance, that two parallel lines intersect in a point at infinity; that all circles in a plane pass through two fixed points at infinity (the circular points), and that two spheres intersect in a fixed circle at infinity. (See GEOMETRY.)

The most remarkable mathematical doctrine of the infinite is that which is associated with the conception of infinite aggregates. In the case of any aggregate it is possible to pair the elements in such a way that each element in the aggregate is paired with an element of the aggregate. Thus in the set 1, 2, 3, we may take 1 with 2, 2 with 3, 3 with 1. In this case the first terms in the pairs exhaust the elements in the given set, and so do the second terms. In any way in which all the elements of a finite aggregate are paired uniquely with elements of the aggregate, the second terms in the pairs (as well as the first) exhaust the aggregate. This is the distinguishing quality of a finite aggregate as finite. The opposite quality characterizes infinite aggregates as infinite. Thus, in the case of the set of all positive integers, we may pair each integer with its double; the first terms in the pairs exhaust the aggregate of positive integers, but the second terms do not, since there is no odd number among them. In general an infinite aggregate is an aggregate such that its elements can all be paired uniquely with a part of its elements. This is the *positive* definition of an infinite aggregate, as opposed to the *negative* definition which characterizes it as one that is *not* finite.

If two aggregates are such that the elements of one may be made to correspond with the elements of the other in such a way that each element of either aggregate corresponds to one and just one element of the other aggregate, the relation so established is said to be a one-to-one correspondence between the aggregates. When a one-to-one correspondence is possible we say that the number of elements in one aggregate is the same as the number of elements in the other. In the case of finite aggregates this agrees with the usual conception of the sameness of number of two aggregates. The question arises whether two infinite ag-

gregates have always the same number of elements; the answer is negative. The number of all integers is the same as the number of all rational numbers, but is less (in a suitably defined sense of the term) than the number of all real numbers. The number of points on the segment of a line is equal to the number on the whole line and in fact to the number in the whole of space, but is less than the aggregate of all functions of a real variable.

See E. W. Hobson, *Theory of Functions of a Real Variable*, vol. I. 3rd ed. (1927), Camb. Univ. Press; B. Bolzano, *Paradoxien des Unendlichen* (Leipzig, 1850); and L. Couturat, *De l'infini mathématique* (1896). (R. D. CA.)

INFLAMMATION AND ITS SEQUELS. The protean character of inflammation is sufficient explanation of the fact that none of the numerous attempts to define the condition has been entirely successful. The term represents the sum of changes locally produced in a living tissue by the action of an irritant, and since the constituents of the tissues and the characters of irritants vary within enormously wide limits, it follows that the phenomena of inflammation vary within wide limits also. Nevertheless, the four "cardinal signs" indicated by Celsus (A.D. 34) viz., redness, swelling, heat, pain, are in varying degrees present in every case of inflammation, and subsequent centuries only added to these four signs, a fifth, impairment of function.

From a clinical point of view inflammation may be acute, sub-acute or chronic, may be widespread or localized, may produce intense destructive changes or little obvious effect, may be relatively unimportant so far as life is concerned, or may endanger life from the outset. Essentially, however, the phenomena are the same in kind though individually varying in degree to an infinite extent. This is true even if the irritant evoking the inflammation be one and the same. The micro-organism known as staphylococcus aureus, lodged in the cardiac valves, produces valvular disease of the heart, with the entire chain of events that valvular disease entails; in the subcutaneous tissues, leads to a pustule; in the liver, to an abscess; within the skull, to cerebral abscess or meningitis, in the superficial layers of the skin, to a pustular dermatitis, to mention but a few examples. Here the different effects depend, in large measure, upon the seat of lodgement of the micro-organisms. Other variations depend upon the specific character of the infecting micro-organism. Lesions produced by B. tuberculosis, Treponema pallidum (syphilis), B. diphtheriae, B. perfringens (gas-gangrene), B. pestis (plague), V. cholerae asiatica, have peculiar characters, so that a cursory examination might fail to discover that essential identity of phenomena which underlies all of them.

Inflammation and Repair.—One of the greatest difficulties in visualizing inflammation lies in the fact that whatever may be the effect of the irritant upon the tissues at the focus of its maximum intensity, that focus is surrounded by concentric zones in which the intensity of the irritant action, by degrees, falls off to zero. In correspondence with this the reaction of the tissues shows concentric zones of variations which, in turn, shade off to zero. An example will make this clear. If a needle be raised to a dull red heat and the point be applied momentarily to the skin on the back of the hand, the reaction which ensues will occupy, say, a circle with a diameter of 0.5 cm. In the centre there will be absolute death of certain epidermal cells, around this there will be a blistered zone, in its turn surrounded by a zone of redness, heat and pain, intense nearest the seat of injury and gradually shading into the normal skin of the periphery as one passes away from the centre. These phenomena depend upon the intensity of the heat acting on the tissues in each concentric zone and the effects of heat on the cells, from the centre outwards, are immediate death, injury so severe that recovery is impossible, injury sufficiently slight that recovery is possible, stimulation to increased normal activity. That increase of normal skin activity may follow on exposure to suitable temperatures is shown by the redness and sweating experienced on a summer day.

The peripheral appearances described above do not occur at the moment that the hot needle is applied, but take some time for their production, and disappear in reverse order until the normal condition of the skin is re-established. That is to say,

the local inflammation is followed by regeneration and repair. It is this essential association of reparative or stimulative processes with destructive or inflammatory processes that renders study of inflammation so difficult, but the two types of process must be entirely distinct, for stimulation occurs in the normal processes of life in which inflammation is completely absent, though these same stimulative processes are responsible for the regeneration and repair that normally follow inflammation. In a word, inflammation is essentially degenerative and destructive, but of necessity brings regeneration and repair in its train. Recognition of this principle is of fundamental importance in treatment, as it indicates that before repair can take place at a given spot every source of irritation, *i.e.*, of inflammation, must be removed. It is intelligible, too, that a tissue on the way to repair may itself fall under irritant action. Then the phenomena of repair and of inflammation are commingled; the result is chronic inflammation.

The Inflammatory Process.—A minute injury like that described above, with the vascular and tissue changes it induces, is an epitome of the phenomena of inflammation in general. Microscopical examination shows that in the inflamed area the blood vessels and the tissue elements are modified. The blood vessels are affected differently in the central and peripheral regions. Towards the centre of the area they are dilated and the blood therein is stationary, the red blood corpuscles have lost their individual contours and channels and blood may be represented by homogeneous red cylinders. Further out the vessels are dilated also, but the blood flow through them, though retarded, has not ceased, and outside the vessel walls are red corpuscles, polynuclear leucocytes and fluid that have escaped from within the lumen. Still further outwards the vessels are dilated and the rate of blood flow is much increased; this zone gradually merges into the region of normality. The essential cells of the part also share in the reaction, showing modifications varying from complete disintegration to cloudiness of cytoplasm and disruption of nuclei. Thus in every example of inflammation there are vascular changes associated with dilatation of vessels, modifications in rate of local blood flow, exudation of fluid, emigration of leucocytes, extravasation of red corpuscles, and disorganization of the essential tissue elements. Such differences as are introduced by variations in the type of injury and kind of tissue involved are differences of degree, not of kind. But, primarily, it is the local increase of blood flow that accounts for the "redness" and "heat," the exudation that accounts for the "swelling" and "pain," the tissue changes that account for the "impairment of function." Obviously, with a given injury, where the tissues are normally loose, *e.g.*, skin of back of hand, swelling will be relatively great, and pain relatively slight; where the tissues are normally tense, *e.g.*, the pulp of the fingers, swelling will be slight and pain great. The lack of distensibility of the teeth, and of the bony sockets of the jaw in which the teeth are set, amply explains the acute pain of toothache.

The phenomena associated with inflammation may be distressing to the patient, but of temporary importance; on the other hand, they may be so excessive that they constitute in themselves sources of irritation to the tissues in which they occur. A blow in the neighbourhood of the knee may lead to local inflammation, with so much pain and effusion that the joint is kept immobile sufficiently long for atrophy, from disuse, to occur in the muscles moving the joint, and occurrence of adhesions within the joint itself. Hence the primary irritant may be reinforced by secondary and subordinate irritants, and in many instances the latter lead to the greater degree of disability. Other examples of the dominating influence of these secondary irritants are seen in cases of pleural and pericardial adhesions, ascitic collections of fluid, necrosed bone (sequestra), renal and biliary calculi. In all instances, however, whether it be by way of primary or of subordinate irritants, the tissue elements involved determine the ultimate effects of the inflammation. According as they are nervous, muscular, renal, connective tissue, or of other kind, the features of the symptoms resulting from the inflammatory lesion are determined, and in proportion as the tissue cells themselves are relatively vulnerable and predominate in the affected region,

the symptoms are produced by relatively low degrees of irritation. Particles of dust that are without effect on the skin or mucous membrane of the mouth may cause profound inflammation of the eye; oil of turpentine which, acting on the skin, merely reddens it, when acting on the secreting cells of the kidney, leads to an intense, possibly a fatal, nephritis.

Irritants, Non-organic and Organic.—Hitherto the irritants that have been mentioned may be regarded as non-living or unorganized, and such irritants are of the widest variety, chemical, physical, mechanical; the strong acids and alkalies, the poison injected by a bee, wasp, or stinging nettle, heat, cold, ultra-violet and other radiations, bullets, sprains, blows, cuts, are a few examples. There is even some reason for believing that, in hysterical subjects, irritants may be psychological, though all such statements must be received with caution in an individual case. In all the above-mentioned instances the irritant action is momentary, or at all events, limited, and the inflammation is correspondingly limited. It reaches its height, and so soon as the primary and consequential subordinate irritants have ceased to be effective, owing to their actual removal, dilution, neutralization, and so forth, the strictly inflammatory processes come to an end and resolution, regeneration and repair (*see below*) come into play.

But there is another, and in most respects, a far more important variety of irritant that leads to inflammation. The irritant here is living or organized, and the group embraces the whole range of pathogenetic bacteria and animal parasites that affect the solid tissues. The inflammatory phenomena are dominated by the fact that the irritant has the power of living and multiplying within the animal tissues, and though, fundamentally, the tissue reactions towards this type of irritant are identical with those towards non-organized irritants, the scales are weighted from the first in favour of the irritant and against the tissue it invades. To produce a given result a smaller initial injury is sufficient when the irritant is bacterial, because the irritant has in the toxin it produces a weapon that the non-organized irritant has not, has in its power of multiplication a power of escaping from the region where the tissues are opposing it and carrying its injurious action to a distance. And in the course of these activities it occasions such pathological conditions as abscess, ulceration, gangrene, necrosis, sepsis, fever, nervous symptoms; and the train of ill-effects extends indefinitely. Whether the patient succeeds in overcoming the primary and secondary irritants, and in repairing the damage they have caused, or succumbs under the attack, is determined by the factors influencing his immunity or susceptibility.

Mode of Operation of Bacterial Irritants.—It follows from what has been said that, theoretically, the entrance of a single pathogenic micro-organism into the tissues is sufficient, and actually the mere prick of an infected needle has in many instances led to severe general illness, sometimes to death. It follows, too, that the sequels of an inflammation caused by an organized (bacterial) irritant are more pronounced, last longer, and induce more damage to the tissues than those following the action of a non-organized irritant of comparable magnitude. This truth lies at the bottom of all antiseptic and aseptic surgery. It also furnishes the main explanation of abscess formation, ulceration, focal necrosis and gangrene, as pathological sequels of inflammation. An abscess, pathologically, is merely a collection of dead tissue cells, polymorphonuclear leucocytes and exuded blood plasma which, at first solid, has become liquefied by the proteolytic action of enzymes. That this destruction of tissue cells, migration of leucocytes, exudation of blood plasma, proteolysis, are on so great a scale that a *macroscopic* abscess results, depends upon the bacterial character of the irritant at work; pathologically, an identical condition, though of *microscopic* proportions occurs preparatory to the healing of every perfectly aseptic wound. For in both instances the irritant (bacteria or knife) causes death of tissue cells, vascular changes, passage of leucocytes and plasma from within the blood vessels to the lymph spaces outside, local coagulation of the exuded fluid and its subsequent proteolysis.

Here the danger must be indicated of considering inflammation

as merely a local process, though one at times affecting a large area. Granted that the local phenomena attract most attention, yet it is clear that the increased local blood flow can only be carried out by a re-arrangement of the circulation over the whole body, that the exuded fluid implies a general re-arrangement of the intra- and extra-vascular relations, that the localized collection of leucocytes, often in huge numbers, implies a redistribution of their numbers within the circulating blood, and often an increased output at the seats of their normal production. The experimental evidence for these statements lies in the altered specific gravity of blood and of tissues at distant parts of the body, and the altered corpuscular constitution of the blood (particularly concerning the numbers of polynuclear leucocytes) that accompany local inflammation. So, too, fever, general discomfort, disordered digestion, altered composition of the urine, are often other indications that the entire body shares in the changes. Finally, the production of specific anti-substances to antagonize bacterial irritants is a function of the tissues (*see* BACTERIA AND DISEASE), and such anti-substances are conveyed by the blood to the region where they are to act, *i.e.*, at the focus of inflammation.

THE SEQUELS

The sequels of inflammation are (a) physiological and (b) pathological. To the latter reference has been made repeatedly in the previous section, and it has appeared that they depend upon persistence of irritant action, whether primary or secondary. These pathological sequels do not call for further remark here. The physiological sequels are those which bring about a restoration of the inflamed part to a healthy condition. In some cases this may consist in a return to the normal, but in the majority the tissue is not exactly the same as it was before becoming inflamed, and often the original tissue is finally replaced by tissue of quite a different kind. The processes at work are termed resolution, regeneration and repair.

Resolution.—By this is meant that the processes indicated by the irritant, on the cessation of its action, return to normal in the reverse order to that in which they were called forth. The classical example of resolution occurs in acute lobar pneumonia caused by *M. pneumoniae*. Here the irritant leads to acute congestion of a large part of the lung, and the dilated blood-vessels pour into the air alveoli inflammatory exudation which coagulates and renders the affected part of the lung airless, solid and more voluminous than when normal. Great numbers of polynuclear leucocytes also pass from the blood-vessels and are entangled in the coagulum, together with small numbers of endothelial cells from the walls of the air alveoli. In an uncomplicated case the irritant action of the micrococcus now comes to an end because the body has elaborated the necessary anti-substances. The coagulated exudation is liquefied by proteolytic enzymes supplied by the polynuclear leucocytes, and the resulting fluid, with any dead and desquamated cells is removed by expectoration, drainage by lymphatics, re-absorption into the blood-stream. The normal calibre of the blood-vessels is re-established, defects in endothelium are remedied by division of neighbouring endothelial cells, the air-ways are re-opened and the lung returns to a condition that cannot be distinguished from the normal. Resolution in this complete sense, though the rule in lobar pneumonia, is the exception in other instances, though joints affected with acute rheumatism may also return to the normal. Even when the part apparently returns to normal, microscopic examination shows that this is not absolutely the case, *i.e.*, that not resolution alone, but repair also has played a part in the recovery.

Regeneration.—The re-formation of tissue in invertebrates is often complete even though a considerable mass has been removed; crustaceans such as the crab or lobster will re-form an entire limb. Amongst the vertebrates such regeneration is much more limited, though an amphibian like the tadpole or newt will re-form a complete tail if it has been removed. In higher vertebrates organs are not regenerated. It is true that if a portion of liver tissue be removed experimentally, the surrounding hepatic cells divide and produce a tissue having certain resemblances to liver tissue, and probably exercising hepatic functions. In some

degree the same is perhaps true of renal tissue. The stimulus of each successive pregnancy, too, leads to a regeneration of uterine muscular, and probably also of mammary, secreting systems. But in the latter examples the meaning of regeneration is strained, and it is an undoubted fact that when uterus or breast has been subjected to inflammatory, as distinguished from physiological, action, *e.g.*, when either organ has been incised for surgical purposes, the defect is not filled by muscular or glandular tissue, but by scar tissue, *i.e.*, regeneration does not occur, but repair. Strictly speaking, in higher vertebrates regeneration to fill an artificial defect is confined to cells of the epithelial, endothelial and connective tissue systems and to blood-vessels. In all other systems a defect resulting from irritant action is repaired; the faulty tissue is not regenerated.

The regeneration of epithelium implies that certain cells of a like kind persist in the neighbourhood of the defect, and by their repeated division are able to re-construct the tissue. Physiologically an example of this occurs in the monthly reconstruction of the tubular glands of the normal endometrium. The bases of these glands reach into the muscular wall of the uterus, and persist when the endometrium, with the greater part of the glands, is cast off in menstruation; it is from these remnants that the entire glands are re-constructed. When a defect occurs in the superficial squamous epithelium, *e.g.*, at the seat of an ulcer, the intact epithelial cells at the periphery divide, and in time cover the denuded space. At the free edge the cells are but one layer thick, but they soon begin to divide parallel to the surface, until the new skin is stratified and several layers thick. This regenerative property of squamous epithelium is utilized in the surgical operation known as Tiersch grafting. Where a large superficial area is devoid of skin, small grafts are cut from normal parts reaching down to and including the germinal layer (*see* EPITHELIUM), and are applied to the granulating surface. Here, when a graft has "taken," it forms a centre for centrifugal growths of epithelium. In this way the covering-in of a large area left by a superficial burn, for example, is materially shortened. The specialized elements of the true skin and subcutaneous tissue, *i.e.*, papillae, touch corpuscles and other sensory organs, sweat glands, sebaceous glands, hair follicles, are not regenerated. Columnar and spheroidal epithelial cells also regenerate provided that corresponding cells persist from which regeneration can take place. When such cells line gland systems the composite system may or may not be regenerated. If the system be simple, *e.g.*, a tubular gland lined by columnar epithelium, it will probably be re-formed; if compound, *e.g.*, a racemose gland lined by spheroidal epithelium, it will probably not be re-formed.

The regeneration of endothelium occurs in one plane only, and it is doubtful whether fibrous tissue cells do not at times replace them in respect of their tegumentary function. The chief regenerative function of endothelial cells is represented in the new formation of blood-vessels, whereby the nutrition of the young tissue being formed to fill the defect is carried out. These new blood-vessels arise from pre-existing capillaries by the local formation of a solid endothelial bud, which grows towards the free surface of the wound and gradually becomes canalized. When two such buds from contiguous capillaries have nearly reached the free surface they bend over, their tips meet, fuse and are canalized; hence the two original capillaries are now connected by a newly-formed capillary loop. The tips of these loops can be seen with the naked eye on the floor of a healing ulcer as minute projecting bright red points or "granulations" that bleed on the slightest rough treatment. Should one of these capillaries ultimately become converted into an arteriole or venule the additional coats are formed by extensions from the corresponding coats of pre-existing vessels. This new formation of blood vessels is known as *vascularization*, and the tissue in which the new capillary loops occur is known as *granulation tissue*.

Regeneration of members of the connective tissue group is one of the most widespread processes following on inflammation. It accounts for the formation of scar tissue in repair of a defect, for the production of adhesions in serous cavities, for the repair of bones after fracture. It also accounts for the increase of

fibrous tissue in conditions like chronic fibrosis of kidney ("granular kidney") and liver (cirrhosis) and sclerosis of bone, though the association of such increased fibrous or bony formation, with an antecedent inflammation is doubtful in some cases. The chief tissues thus regenerated are fibrous tissue with its variants, fatty and mucoid tissue, neuroglia and bone. In all instances the new tissue is formed from pre-existing cells, fibroblasts in the case of fibrous tissue, neuroglia cells in the case of neuroglia, periosteal and endosteal osteogenetic cells in the case of bone. Cartilage both yellow elastic and white hyaline, is regenerated with far less frequency, especially the former variety; their place when destroyed is usually taken by white fibrous tissue. When regenerated the new material is formed from pre-existing remnants of cartilage, but there is reason to believe that in some cases of bone regeneration a cartilaginous stage is interposed between the fibrous and osseous stages, as in the normal formation of bone through cartilage. Usually, however, repair of bone takes place by direct calcification and ossification without the interposition of a cartilaginous stage, thus resembling so-called membranous bone formation. In all essential details the newly-formed fibrous tissue or bone resembles the normal tissue, but often it ends by being denser and less regular in its general arrangement. Corresponding with this, cells are more scanty and the inter-cellular substance more pronounced. Calcium salts may be deposited in fibrous tissue formed as a sequel to inflammation, as in the calcareous nodules occurring in pleuritic or pericardial adhesions, or it may become the seat of overgrowth reminiscent of tumour formation (keloid). In all cases the amount of fibrous tissue formed after inflammation is excessive, at least at first, but for some reason that is not fully clear, inflammatory fibrosis reacts readily to X-radiation, so that redundancy is often treated successfully by this means.

In the case of nerves, the term regeneration is often used, but the return of function which may be observed after the severed ends of a nerve have been sutured, is not regeneration in the strict sense. In all the instances described above, regeneration of tissue depends upon re-formation of cells by division of pre-existing cells, but nerve cells once destroyed are never re-formed, and the return of function depends merely upon centrifugal growth of the axis cylinder from the still intact nerve cell along the scaffolding provided by the anatomical nerve, whose continuity has been restored by suture. Experiments that have been regarded by their authors as indicating that the functional nerve is restored by longitudinal apposition of proliferated neuroglial cells, do not carry conviction.

Repair.—The phenomena described above play varying parts in the production of repair, so that the interaction of inflammation and repair and the essential similarity of processes in clinically dissimilar conditions can best be brought out by tracing them in a few illustrative cases.

(1) *An Aseptic Surgical Wound.*—The irritant here is the knife, and subordinate irritants are reduced to a minimum, probably being represented by the stitches, a small number of tissue cells on the cut surfaces that are injured beyond recovery, and small amounts of blood clot. As the result of these local dilatation of vessels occurs, exudation is poured out in the superficial layers of the opposed cut surfaces, and between them and by coagulation, temporarily binds them together. Polynuclear leucocytes migrate from the blood stream and by phagocytosis (*q.v.*) remove dead tissue and remnants of blood clot, and later the fibrin filaments of the coagulum. At the same time newly-formed capillaries bridge the gap between the two cut surfaces, travelling along the fibrin filaments in the intervening coagulum. Fibroblasts, derived from pre-existing connective tissue corpuscles, range themselves along the new capillaries and build up fibrous tissue whereby the two opposed surfaces are definitely united. On the surface, squamous epithelial cells divide and fill the skin defect and healing is complete. As the newly-formed fibrous tissue grows older it contracts and obliterates the majority of the newly-formed capillaries, so that the scar tissue, which at first was red and excessive, becomes dead-white and contracted.

(2) *Fracture of a Long Bone.*—(a) the fracture is simple and

aseptic. Here the irritant is the force that leads to the fracture, and subordinate irritants, consisting of effused blood from ruptured blood-vessels, torn muscles and ligaments, ruptured medulla of bone, play an important part in respect of their volume, while movement between the fractured ends of the bone may further enhance these. Nevertheless, coagulation of the effused blood occurs about the ends of the bones and holds them together as a preliminary. The essential difference between the processes here and those obtaining in an aseptic surgical wound consists in the greater mass of material that has to be removed, the greater space that has to be bridged by newly-formed capillaries, the greater distance the migrated polynuclear cells have to travel, and the fact that the endosteum and periosteum, with their osteogenetic cells, are involved instead of white fibrous tissue. In time the blood coagulum around, between and within the fractured ends of the bones, is replaced by a mass of soft bone (temporary callus) derived from periosteum and endosteum, and of this the greater portion is ultimately removed by osteoclastic (*i.e.*, phagocytic) action, while between the fractured ends there remains newly-formed bone that becomes denser and unites the fracture (definitive callus). Where the fractured ends are widely separated bony new formation may be impossible and the ends are united, if at all, by fibrous tissue: (b) the fracture is compound and septic. Here the irritant action is increased by the presence of pathogenetic bacteria and their toxins in damaged, dying and dead material resulting from the fracture itself. The pathological sequels of inflammation, suppuration and necrosis, are therefore superposed upon the already important secondary irritants occasioned by the fracture. Even assuming that the bacterial infection does not become generalized and lead to septicaemia or pyaemia (*see* SEPSIS) the original amount of damage to tissues will be increased by that amount, which is due to the bacterial action as such. When and if these potent adjuvants of the original irritant action have been overcome, and only at those spots at which this occurs, do strictly reparative processes take place, but they are identical with those occurring in an aseptic fracture. In other words, the first object of the body is to render the condition aseptic, and this object the surgeon copies in his treatment of every compound fracture. It can be understood that whereas the healing of an aseptic surgical wound with surfaces well apposed is a matter of days, the healing of a simple, aseptic fracture of bone is a matter of weeks, and the healing of a compound, septic fracture is one of months.

(3) *A Focus of Pulmonary Tuberculosis.*—Here the primary irritant is *B. tuberculosis*, and an apparent difference from the processes summarized above lies in the facts that the reaction of the lung tissue to the bacillus is cellular only, and contains so-called giant cells, and that blood vessels are absent from the minute nodule or tubercle. The caseation so characteristic of tuberculosis is dependent upon these differences (*see* TUBERCULOSIS), which are correlated with the relative chronicity of the process. But the tubercle when formed, besides replacing a certain amount of lung tissue, is a foreign body, and as such leads to inflammation in the surrounding tissues, often with a degree of congestion that explains the haemoptysis that may accompany early tuberculosis. If it be situated on the surface of the lung the tubercle induces inflammation of the pleura, local death of endothelial cells, and subsequently the production of fibrous tissue in the form of a pleural adhesion. Within the lung itself the tubercle, after undergoing caseation and, perhaps, calcification, becomes surrounded by fibrous tissue in the same way, and by the same local proliferation of fibroblasts, that a fibrous capsule is formed around an aseptic bullet lodged in the tissues. Should the tubercles be numerous and uncomplicated the resulting fibrosis may be irregular and extensive, and should the lesion be complicated by access of pyogenic micro-organisms, suppuration and the formation of a phthisical abscess cavity (*vomica*) are super-added. But even in the latter case, if the primary and subordinate irritants be overcome, the defect of lung is repaired by newly-formed fibrous tissue, which is as surely scar tissue as in any of the other instances that have been adduced.

(4) *An Abscess and an Ulcer.*—These two conditions are

bracketed because an ulcer may be regarded as an abscess from which part of the wall restraining the pus is wanting. Hence the pus produced on the floor of an ulcer drains away as it is formed, whereas in the abscess it accumulates within the abscess cavity. Microscopically, however, the floor of an ulcer and the wall of an abscess are composed of the same elements arranged in the same fashion. When the bacterial irritant has become lodged within a tissue, and has multiplied sufficiently and produced enough toxin to destroy the neighbouring tissue cells, by the ordinary processes of inflammation it produces a hard, hot, painful swelling which consists of coagulated exudation, numbers of polynuclear leucocytes, dead tissue cells, and living and dead bacteria, the central part becoming liquefied later by proteolytic action and constituting the pus. This focus of inflammation is surrounded, as has been said earlier, by a zone in which the irritant action has fallen off in intensity to a level at which it ceases to be an irritant and becomes a stimulus. At some less or greater distance from the focus of inflammation, therefore, the necessary factors for the formation of new capillary blood vessels, the proliferation of connective tissue cells and the production of young fibrous tissue, *i.e.*, the formation of granulation tissue, are present. Obeying hydrostatic laws, the pus within the abscess "points," and by destruction of superficial layers of tissue, ultimately escapes. Relieved of this subordinate source of irritation the wall of the abscess contracts, and the reparative fibrous tissue constituting the wall goes on to the formation of definite scar tissue instead of breaking down to swell the contents of the abscess. It is at this stage that the abscess and ulcer are identical in composition. In both instances the most superficial layers of the granulation tissue break down into pus, which drains away, and the final healing only takes place when the surrounding epithelium (or in the case of an abscess in an internal organ covered by serous membrane, the endothelium) has regenerated a covering for the newly-formed scar tissue, and has thereby eliminated the possibility of bacterial irritant action.

By application of the principles outlined above a rational explanation of most examples of inflammation and the phenomena associated therewith can be obtained. Naturally, factors arise that are difficult, even impossible in our present state of knowledge, to explain. One of these is the relation of irritative to stimulative action. According to some authorities, the repair that follows inflammation is initiated by hormones produced by the injured tissues. They see in the formative processes following inflammation something akin to the processes which, under other conditions, lead to the production of neoplastic tumours. (W. S. L.-B.)

INFLATION AND DEFLATION. If we define inflation as an abnormal increase in the quantity of purchasing power, and deflation as an abnormal decrease in the quantity of purchasing power, the first issue which arises is: under what technical conditions are inflation and deflation respectively possible? This question cannot be answered without taking into account the circumstances which lead to inflation and deflation. Inflation is necessarily accompanied by a fall in the value of money per unit: deflation is accompanied by a rise in the value of money per unit, and these changes in the value of the monetary unit in themselves mainly depend upon the degree of inflation and deflation and on the psychological reactions thereby set up.

The object of inflation is not the increase in the volume of purchasing power for its own sake. Purchasing power is increased for the purpose of increasing the consuming power of a given social group. In the modern world the two groups of most importance in this connection are Governments and business men (including both producers and traders). Governments require consuming power at all times, but particularly in periods of war, and in this case require it on an unlimited scale. For psychological reasons that is, "to keep up the war spirit" heavy taxation is unpopular. Borrowing in a form which diminishes spending power by the lenders has equally its limits. Governments resort to inflation, to an increase in the volume of money, and, since they can alter legislation if that stands in the way, they proceed to do so. The fundamental condition is that if inflation is to be practised the currency must no longer be fixed in amount. This

implies in practice that the currency, if linked directly or indirectly with a metallic standard, must be released from such dependence. It must be made inconvertible into gold or foreign exchange, and must be freed from any legislative limit restricting its amount. Business men desire to borrow more whenever they believe that trade prospects are improving. If the currency is linked to gold or some other metal, their borrowing has the effect of imperilling the gold or foreign exchange reserves of the banking system. The consequence is that the banks in their own interests are driven to restrict inflation to the degree consistent with the maintenance of the standard. Government relieves, or can relieve the banks of any such limit, and, having freed the banks, can bring powerful pressure to bear to exploit the freedom conferred.

Abolition of Metallic Standards.—To sum up: unlimited inflation involves the abolition of metallic standards. Governments can achieve this more easily than business men. Hence inflation pursued for the benefit of Governments can be carried to much further lengths than inflation for the benefit of the business classes. And, in fact, experience bears this out. The ten or 15% variation in prices which is associated with the cyclical movements of trade weigh very lightly in the scale compared to the enormous variations in the value of money during the last ten years. But once an inflationist movement has been begun by Government it may be continued by industry, as happened in 1919 to 1920 in the United States.

Deflation to be possible to an unlimited extent also requires a currency system not linked to any metallic standard. But, in contradistinction to inflation, it is not likely to be carried to any considerable extent, even if the technical conditions permit of it. Deflation involves a rise in the value of money and therefore increases the value of debts. Even if, in the interests of prestige or of social justice, a Government desires to deflate, it will hesitate to do so if the amount of deflation required is considerable: it would prefer to *devalue* the currency, that is, to give it a fixed value in terms of gold lower than the value before inflation. In practice, since inflationary legislation does not repeal the right to obtain currency for gold or foreign exchange but only the right to obtain gold or foreign exchange for currency, the limit to deflation comes when the local currency threatens to become more valuable than gold: gold is then presented in exchange for local currency and the fall of prices is checked. When deflation is enforced by banks in order to restore their reserves of gold or foreign exchange after they have been threatened by a business boom the amount of deflation involved is relatively small because the previous degree of inflation has been small also.

The pursuit of an inflationary policy by Government necessarily involves an "unbalanced budget," that is, a budget which can only be balanced if the surplus of expenditure over revenue is met by means of inflation, so long as the Government inflates by means of its own notes. If the inflation takes the form of loans by a bank to those who only borrow for re-lending to Government, there will be concealed inflation. When a Government proposes to deflate, that is, to reduce its own note circulation, it must necessarily have a surplus: that surplus of income over expenditure it applies to wiping out the excess notes. When it has itself borrowed from a bank, it must use the surplus to cancel indebtedness to the bank and the bank must use the proceeds to cancel notes. The same is true when the Government has borrowed from third parties, who have themselves borrowed from a bank. The surplus revenue flows from the Government to its creditors, from these to the lending bank or banks, and is by them utilised to cancel purchasing power. If the banks were to re-lend the money repaid to them, there would be no deflation. In the case of inflation and deflation originating in connection with the movements of trade and production, there is of course no difficulty in understanding how the purchasing power is issued and withdrawn: inflation swells the commercial loans and the liabilities of the banks to their customers: deflation involves repayment of loans, a reduction of the assets in the shape of discounts and overdrafts and a cancellation of deposits and of currency.

Economic Limits.—The technical questions so far discussed throw no light on the two main problems connected with inflation and deflation: viz., the economic limits to the processes and their social consequences. The limit which is set to inflation is given by the progressive fall in the value of the currency issued, which, as experience has shown, proceeds in the end at a rate much more rapid than the quantitative increase in the currency itself. The result is that as the quantity rises, the profit to be made out of the issue of further currency diminishes more than in proportion to the amount of issue. Thus, at the end of 1919, the aggregate German currency stood at 41 milliards of marks, which still possessed a gold value of 11 milliards of gold marks. At the end of 1923, the total amount of issue stood at 74,954,803 billions (that is, 12 noughts omitted) and yet this inconceivable amount of currency had a value of only 722 millions of gold marks, on the basis of the dollar exchange. The 56 milliards of roubles in circulation at the end of 1918, had still a value of some 376 million dollars on the most favourable estimate; by the end of 1922 the 1,479,218 milliards had a value of only 69 million dollars at most. Whilst the net revenue accruing to the issuer thus ultimately falls almost to vanishing point disastrous results are produced in the sphere of public finance generally. For, owing to the fact that an interval of time necessarily elapses between the assessment of a tax and its collection, the proceeds of taxation do not keep pace with the decline in the value of money. The State thus finds itself with only a single resource available, and that one of diminishing value. On the other hand, though the fall in the value of money means a progressive diminution in the burden of national debts (from this point of view inflation is equivalent to repudiation) its other expenses mount with the price level. For a time the rise in expenditure can be held down by non-adjustment of salaries and wages: this device cannot be made use of indefinitely. In short, there is a limit to inflation: arising from the progressive fall in the value of the money issued (and this is a sign of the increasing unwillingness to accept it), and the consequential unprofitableness of trying to issue more of it.

The unwillingness to accept a currency the value of which is constantly falling is part of the very complex economic consequences which flow from inflation, consequences which have been illustrated on a tragic scale in Europe, in particular in the period 1919 to 1925, because the degree of inflation was then far in excess of anything previously known.

Economic Consequences.—In discussing economic consequences, a distinction must be drawn between the effects of inflation on *particular social classes* and on the *national economy as a whole*. Particular social classes gain or lose relatively to one another, according as to whether their income in terms of money keeps pace with the fall in the value of money or not. The recipients of incomes fixed in amount, whether by law or custom, suffer in proportion to the rigidity of their income and the rise in the price level. The higher classes of civil servants, teachers, professional men paid by customary fees, the owners of fixed interest-bearing investments, pensioners and the like all suffer. On the other hand, individuals whose incomes are adjusted to the changes in the price level need not suffer or gain anything at all, except when the changes in the price level are so rapid that it is impossible to keep pace with them. The wage-earning class as a whole comes into this intermediate category, though the position of the skilled worker is usually worse than that of the unskilled in respect of the adjustment of wages to price levels, and in all cases there is in the early stages of inflation a time-lag which is due to ignorance of what is happening. Lastly come those classes of the community whose incomes represent residual gains: ordinary shareholders and business men generally, whose incomes are derived from the margin between selling prices and expenses. These benefit from inflation, since their costs do not all of them rise as rapidly as the price level rises. The proportion of the total real income of the community which falls to their lot goes up in periods of inflation. But, though the relative position may alter to their advantage, their absolute position may be worse than it was before, in common with the absolute worsening

of the position of other classes, for the reason that inflation may reduce the total productivity of society, and is certain to do so if carried to great lengths.

Inflation, in so far as it is relatively moderate, will not much affect the willingness to hold money, and operates simply to increase the proportion of the total income (real and nominal) falling to the beneficiaries of inflation. But rising prices act as a stimulus to producers and to this extent invigorate forces tending to mitigate the rise in the price level, whilst at the same time unemployment falls, since real wages lag a little behind prices and the real cost of labour to the employer therefore falls. But if inflation reaches such a stage that the fall in the value of money becomes obvious everyone will try to protect himself against the further fall which is then expected. Goods are bought so far as they are available: everyone will hold real things, if possible, rather than money. The liquid capital, that is, money stocks of employers, diminishes in value: they try to protect their profits by expanding their fixed plant. Traders holding stocks of goods will be reluctant to sell since prices may go up still more. The workers push up money wages and, the time-lag being wiped out, a particular source of profit to employers disappears. The "flight from the currency" withdraws part of the funds available abroad, so that the supply of raw materials, etc., falls off. The constantly rising price level produces "paper profits" and stimulates extravagance. The result of all these factors is that there is a maldistribution of capital between fixed and liquid forms: that the aggregate of all savings declines and that the national income falls off in total amount. In the end no one has benefited from inflation; everyone would have gained from its cessation at an earlier stage.

The direct effects of deflation on the relative position of different social classes are the opposite of those of inflation. Deflation involves falling prices; it therefore reduces the money yield of taxation, reduces the profits of business men and of traders, and adds to the real income of all classes of the population whose money incomes are fixed, whilst prices are falling. It has therefore the effect of increasing the weight of all fixed debts; a particularly important matter after a great war when the National Debt stands at a large figure. Since deflation involves falling prices, it increases the volume of unemployment and diminishes the inducement to hold stocks of goods, since these are falling in value. On the other hand, since prices are falling deflation makes saving easier, and since it involves, owing to industrial depression, a slackening in the demand for fresh industrial capital, it is accompanied by falling interest rates, which facilitate conversion operations and thus mitigate the burden of fixed charges. The falling yield of taxation is thus offset in part, by the fall in expenditure on current goods and services, in part by the fall in interest rates.

For reasons already set forth, the practical limits of deflation are reached sooner than the practical limits of inflation. Severe though the sufferings imposed by deflation may be (particularly when represented by widespread unemployment) it is not doubtful that the sufferings actually covered by inflation have in Europe been much greater than those imposed by deflation; for the degree to which the value of money has been raised by deflation has never been equal to the degree to which inflation has in special cases reduced it. (See further, *QUANTITY THEORY OF MONEY; MONEY; CURRENCY.*) (T. E. G.)

INFLEXION, the action of bending inwards, or the condition of being bent or curved (from Lat. *inflectere*, to bend). In optics, the term "inflexion" was used by Newton for what is now known as "diffraction of light" (*q.v.*). For inflexion in geometry see *CURVE*. Inflexion of the voice is a change in tone, pitch or expression. In grammar (*q.v.*) inflexion denotes the changes which a word undergoes to bring it into correct relations with the other words with which it is used. In English grammar nouns, pronouns, adjectives (in their degrees of comparison), verbs and adverbs are inflected.

INFLORESCENCE, the arrangement of the flowers on the axis, or the ramification of the floral axis, composed of the *rachis*, which forms the stalk supporting the flower or cluster of flowers,

called the *peduncle*. A flower having no stalk is called *sessile*. The floral axis may be shortened, assuming a flattened convex or concave form and bearing numerous flowers as in the artichoke, daisy, etc. There are two distinct types of inflorescence (1) *indeterminate, indefinite* or *axillary* and (2) *determinate, definite* or *terminal*. A third series of inflorescence is termed *mixed*. In the *compound indefinite* inflorescence the lateral shoots develop centripetally upon a primary axis into a group of racemes or compound racemes. See FLOWER.

INFLUENCE, in astrology (*q.v.*) an ethereal fluid, supposed to flow from the stars, which affected the course of events on earth and the destiny and character of man. The word is derived from Lat. *influerē*, to flow in. For the law as to "undue influence" see CONTRACT.

INFLUENCE LINE, in engineering, a curve showing, for one component part of a beam or truss, the shearing force, bending moment, stress or deflection for all positions of a moving load. (See BRIDGES: Construction.)

INFLUENZA. The term influenza will be used to imply "a pandemic outburst of disease characterized, clinically, by a rapid course, catarrh of the respiratory tract, pyrexia and some degree of prostration; and epidemiologically, by a tendency to occur in several successive waves at short intervals of time." This provisional definition is applicable to the visitation of 1918-19, and to other outbreaks of febrile respiratory catarrh more remote in time and about the distribution of which less is known, but is not applicable to the sporadic cases or even the localized epidemics of respiratory catarrh to which the name influenza has been so often applied, especially in the years following fairly closely upon pandemic outbursts.

The Influenza Pandemic of 1918-19.—This pandemic swept over the world in three successive waves, the first appearing quite suddenly in May and June 1918, the second starting at the end of September or early in October and waning in December, and the third wave, less uniform in character, appeared early in March 1919. This outbreak, attributed by France to Spain, by Spain to France and by America to eastern Europe, seems to have appeared almost simultaneously amongst the nations on the Western front, and showed the explosive character that is possible only for a highly invasive infection assisted by conditions of swift communication such as obtain in modern war.

This first wave made its appearance a little later amongst the Central Powers and their neighbours. Early in July it attained its full proportions in Germany, Austria, Norway, Sweden and Denmark, Holland and Switzerland. In several large areas of the world's surface, in the South American republics, in Bermuda, the British West Indies, the Azores and in the islands of the Pacific and Australia, the summer of 1918 passed without an influenzal outbreak. In New Zealand, cases are said to have appeared in August, the harbingers, perhaps, of the autumn, rather than the first manifestations of the summer, wave.

This first wave passed rapidly, so that a "frequency curve" by weeks, in which the incidence in the worst week is taken as 100%, shows a steep ascent to a maximum, followed by an equally steep and almost symmetrical fall, the whole episode passing within a few weeks. The death-rate was inconsiderable, but there was an ominous tendency to a higher mortality amongst the later cases, just before the wave came to an end, seeming to suggest an increase in virulence. The first batch of cases looked "like a mild attack of measles without a rash." Respiratory catarrh, congested conjunctivae, headache, lassitude, pyrexia of short duration, a feeling of prostration with the return of temperature to normal, and then a rapid recovery of health; such was the course in the vast majority of the cases during the first wave. Complications were almost unknown. A few cases which developed broncho-pneumonia or haemorrhagic oedema of the lungs towards the end of the wave sent up the case mortality. In all these characters, the first wave closely resembled the outbreak of 1890, except that in 1890 the death-rate was greatest amongst the middle-aged and elderly, while in 1918 the chief sufferers were amongst the "young adult" groups.

The Second Wave.—Towards the end of September or early

in October, the second wave suddenly gathered force and swept over the world. St. Helena is said to have escaped. Mauritius, too, had a reprieve; and the quarantine measures applied by Australia were successful for the moment but this fatal pandemic spread throughout Europe, America, Asia and Africa.

The upward curve of morbidity was almost precisely similar to that of the summer and the maximum was reached as quickly as in the previous wave, but the fall was much slower and less regular. The outstanding difference between the two waves was the marked tendency to pulmonary complications and the high death-rate of the second. The singularly uniform syndrome of the summer epidemic gave place, in the autumn, to several varieties of clinical picture depending on varying combinations of several factors, amongst which might be reckoned the virulence of the microbic invader, the resistance of the patient, the nature of the bacterial flora of his respiratory tract, and environmental conditions such as occupation, wages and housing. As a rule, the attack was ushered in by the catarrhal and pyrexial symptoms noted in May and June. In many cases, especially where circumstances permitted of immediate rest and treatment, the disease took a favourable course towards recovery, although prostration was clearly always a more marked feature than in the summer. In others, the early pyrexial catarrh was sometimes followed by intense toxæmia leading so rapidly to a fatal issue that there was no time for pulmonary complications to develop. But frequently the lungs became severely affected and the patient passed into a state of anoxæmia recalling that due to exposure to the "pulmonary irritants" of gas warfare.

But there was a formidable difference between the two conditions. While the "phosgene" patient had to deal with a sterile exudate, evoked by a chemical irritant and capable of rapid absorption if vitality was maintained, the lungs of the influenza patient were charged with an exudate evoked by a living virus which had already overcome tissue resistance and could offer to "secondary invaders" conditions of symbiosis favourable to their growth. Here lay the danger. The virus of influenza could open, as it were, the door to the *streptococci*, *pneumococci*, *staphylococci* and other organisms normally held within safe numerical limits upon the respiratory mucous membrane. The *post-mortem* appearances, while tending to have certain basal characters in common, varied considerably with the nature of the "secondary invaders" and other factors. In nearly all cases, there was a haemorrhagic tendency not often seen in other acute lung affections; and this sometimes amounted to a haemorrhagic oedema involving the greater part of both lungs. "Wet lungs," "dripping lungs," were expressions frequently heard in the *post-mortem* room. Areas suggesting haemorrhagic infarcts with their bases extending under the pleura were often noticed. The cut surface of the lungs showed, as a rule, peribronchiolitis and patches of broncho-pneumonia with a general state of oedema throughout the parenchyma of the lung; or a whole lobe might give the appearance of red, or in older cases, grey hepatization (see Major Tytler, R.A.M.C., *Special Report Series No. 36*, Med. Res. Coun., 1919). The third wave had no distinctive characters. It resembled the first wave rather than the second, though pulmonary complications and fatal cases were fairly numerous.

Etiology.—As to the causative organism of influenza we remain, even now, still in doubt. The view that the *Bacillus influenzae* (Pfeiffer) was the cause of the disease, received little support from investigations carried out since 1918. This work was directed, for the most part, to the search for a "filter-passing virus." During the second wave of 1918, the researches of C. Nicolle and Lebaillay in the French war zone, of H. G. Gibson, F. B. Bowman and J. I. Connor at Abbeville, and of J. A. Wilson at Étaples, in the zone of the British armies in France, afforded highly significant evidence in favour of a filterable virus, although the restrictions imposed upon bacteriological work by war conditions and the transitory nature of the epidemic rendered conclusive findings impossible.

In 1919, an investigation was undertaken by Zamanouchi, Sakakami and Iwashima, in which the filtered and unfiltered emulsions of sputum from 43 cases of influenza were injected

into the throats and noses of 24 healthy volunteers, six of whom had recently suffered from influenza. Of the 18 previously uninfected persons, all developed influenza after an interval of two or three days, but the six who had had the disease remained in good health. Similar results were obtained with the filtered blood of patients. At the same time, the spraying of cultures of Pfeiffer's bacillus, sometimes "pure," sometimes mixed with other respiratory bacteria, into the throats of 14 healthy persons failed to lead to illness of any kind.

P. K. Olitsky and F. L. Gates in the laboratories of the Rockefeller Institute for Medical Research were able to approach the subject with much more deliberation and with a much better equipment than was available in France; and their results are proportionally more convincing. Like Gibson and his co-workers, they produced in rabbits a condition closely resembling human influenza by means of filtered or unfiltered nasal secretions taken from human patients during the earliest stages of the attack. They provided independent confirmation of the discovery of Gibson and Bowman that "cultures" in Nogouchi medium were capable of transmitting the disease to animals, and showed that the anaerobic and filterable organism thus cultivated retained its activity after long exposure to glycerine and possessed antigenic properties. To the minute organism isolated by them in the course of this inquiry, they gave the name of *Bacterium pneumosintes*.

Their work received speedy confirmation at the hands of Dr. M. H. Gordon, C.M.G., F.R.S., in the course of an influenzal outbreak among the nursing staff of St. Bartholomew's hospital, London, in 1922. Still further support for a "filter-passer" as the virus of influenza was later provided by Sir Spenser Lister in South Africa. These independent inquiries, leading to similar findings in America, England and South Africa, go far to establish the "case" for a filterable virus as the causative agent of influenza; but caution is still needed in drawing final conclusions until a more precise knowledge is available as to "filter-passers" in general (see FILTER-PASSING VIRUSES).

Epidemiology.—In the absence of final knowledge as to the causative agent, many points of fundamental importance still remain obscure.

The first wave coincided with the arrival of the first drafts of American troops in Europe, who must have brought into common circulation pathogenic strains long dormant in isolated and relatively immunized communities. The crowded troopships afforded just the incubation places that would permit of the maturation of such an infection; and Europe, with its crowded concentration areas and billets, offered an unequalled opportunity for its spread. The last influenzal pandemic had occurred just 28 years before. There might be a few scattered "carriers" and perhaps some residual immunity among the middle-aged and the elderly; but the adolescents and the young adults would in 1918 be "virgin soil." It was just these lower age-groups that suffered most.

How, then, explain the second wave with its greater severity?—and the third? Surely, if immunity played a part, these waves should have been much less extensive, much more benign, and confined to those persons who had previously escaped. These are good, but not final, arguments. The passage of the first wave may have left behind it a virus of exalted virulence, many "carriers" and many "allergic" subjects whose behaviour to reinfection might betray the phenomena of hypersensitiveness of the respiratory surfaces and a tendency to inflammatory exudates on contact with the air-borne virus. Under such conditions a fresh outbreak would be specially likely to arise in the fall of the year, a period of rapid fluctuations of temperature when the chill evenings drive men into the warmth and close contact of crowded dug-outs, shelters and billets.

It is impossible to believe that the so-called "influenza" to which deaths were attributed every year between 1892 and 1918 was the same disease as the fulminating pandemic that followed. Apart from the extreme contrast in invasive power, the distribution of "influenza" mortality by age-groups emphasizes the essential difference between, let us say, the death-rates for 1917 and 1918, the one having a preponderating death-rate amongst the old, the other, amongst the young. Such differences can hard-

ly leap into existence within a few months. The known facts of increase and diminution of bacterial virulence do not support the idea that such a vast alteration is probable or even possible in so short a time.

Acquired Immunity.—Evidence that morbidity and mortality were less marked, in the second wave, amongst those who had been attacked in the first, when thoroughly analysed (*Rep. Min. Health*, 1918-19), was found to indicate that "these data show a considerable immunizing power in the summer attacks and we conclude, although with natural hesitation, that it is probable, on the average, that an appreciable degree of active immunity was attained by those who passed through an attack in its first and mildest manifestations."

The evidences for immunity are of varying efficiency in different places, and the populations of many areas show no tendency to acquire resistance to infection as judged by a comparison between the behaviour of those attacked and those missed by the first wave when confronted by the second.

We believe these data to be unsound as a basis for comparison. It is highly probable that many persons were infected during the summer and yet failed to show appreciable illness. The vast difference that may exist between the numbers *infected* and the numbers *affected* by a bacterial invasion can be judged from what we know of the meningococcus and the diphtheria bacillus. And yet these latent infections may confer active immunity, as we know from the "Schick Reaction" in the case of diphtheria and from other examples. The mere fact of a previous "attack" is not a safe guide in classifying populations for inquiry as to their relative immunities. The best evidence of the acquisition of immunity is to be found in the phenomena of natural recovery of the individual and of the disappearance of pandemic waves from the community. The fact that these groups of pandemics are separated by long and fairly regular intervals, as a rule about 20 years, is not without significance in this connection, since at least this period might be necessary to reduce the residual "immune population" from the last pandemic to an ineffective number.

Artificial Immunity.—No vaccine can be entirely satisfactory unless it is known to contain the virus or germ of the disease in question. The vaccine issued by the War Office and afterwards by the Ministry of Health was confessedly of a provisional nature since the causative agent was still uncertain. Its formula was as follows:—

	Per cu.cm. of vaccine
Bacilli influenzae (Pfeiffer).....	400,000,000
Pneumococci	200,000,000
Streptococci	60,000,000

Unless Pfeiffer's bacillus be accepted as the causative agent, this vaccine must be described as consisting entirely of the "secondary invaders." As such, its issue was entirely justifiable and its effects were such as might be expected: satisfactory in diminishing complications and mortality but practically *nil* in preventing the disease. Vaccine, then, cannot, as a prophylactic, help us much at present; nor can we, in the light of recent experience, hope for great results from general measures of hygiene.

Symptoms.—These vary somewhat in different epidemics but in the main they accord with the description given by Dr. Bruce Low from observations made in St. Thomas's hospital, London, in Jan. 1890:—

The invasion is sudden; the patients can generally tell the time when they developed the disease; e.g., acute pains in the back and loins came on quite suddenly while they were at work or walking in the street, or in the case of a medical student, while playing cards, rendering him unable to continue the game. A workman wheeling a barrow had to put it down and leave it; and an omnibus driver was unable to pull up his horses. This sudden onset is often accompanied by vertigo and nausea, and sometimes actual vomiting of bilious matter. There are pains in the limbs and general sense of aching all over; frontal headache of special severity; pains in the eyeballs, increased by the slightest movement of the eyes; shivering; general feeling of misery and weakness, and great depression of spirits, many patients, both men and women, giving way to weeping; nervous restlessness; inability to sleep, and occasionally delirium. In some cases catarrhal symptoms develop, such as running

at the eyes, which are sometimes infected on the second day; sneezing and sore throat; and epistaxis, swelling of the parotid and submaxillary glands, tonsillitis and spitting of bright blood from the pharynx may occur. There is a hard, dry cough of a paroxysmal kind, worst at night. There is often tenderness of the spleen, which is almost always found enlarged, and this persists after the acute symptoms have passed. The temperature is high at the onset of the disease. In the first twenty-four hours its range is from 100° F. in mild cases to 105° F. in severe cases.

Several writers have distinguished four main varieties of the disease—namely, (1) nervous, (2) gastro-intestinal, (3) respiratory, (4) febrile, a form chiefly found in children. Clifford Allbutt said, "Influenza simulates other diseases." Many forms are of typhoid or comatose types. Cardiac attacks are common, not from organic disease but from the direct poisoning of the heart muscle by influenza.

Perhaps the most marked feature of influenza, and certainly the one which victims have learned to dread most, is the prolonged debility and nervous depression that frequently follow an attack. In the Paris epidemic of 1890 the suicides increased 25%, a large proportion of the excess being attributed to nervous prostration caused by the disease. Of insanities traceable to influenza, melancholia is twice as frequent as all other forms put together. Other common after-effects are neuralgia, dyspepsia, insomnia, weakness or loss of the special senses, particularly taste and smell, abdominal pains, sore throat, rheumatism and muscular weakness. The feature most dangerous to life is the special liability of patients to inflammation of the lungs. This affection must be regarded as a complication rather than an integral part of the illness.

The deaths directly attributed to influenza vary in different epidemics and at different times in the same epidemic, but on the whole, are few in proportion to the number of cases. In the milder forms it offers hardly any danger to life if reasonable care be taken, but in the severer forms it is a fairly fatal disease. In eight London hospitals the case-mortality among in-patients in the 1890 outbreak was 34.5 per 1,000; among all patients treated it was 1.6 per 1,000. In the army it was rather less.

The infectious character of influenza having been recognized, suggestions were made for its administrative control on the familiar lines of notification, isolation and disinfection, but this has not hitherto been found practicable.

There is no routine treatment for influenza except bed. In all cases bed is advisable, because of the danger of lung complications, and in mild ones it is sufficient. Severer ones must be treated according to the symptoms. Quinine has been much used. Modern "anti-pyretic" drugs have also been extensively employed, and when applied with discretion they may be useful, but patients are not advised to prescribe them for themselves.

IN FORMA PAUPERIS: see PRACTICE AND PROCEDURE.

INFORMATION, in English law, a proceeding on behalf of the crown against a subject otherwise than by indictment is either criminal or civil. Criminal informations are *ex officio* or by the Master of the Crown office. An *ex officio* information is a proceeding in the King's Bench by the attorney-general without the intervention of a grand jury. The attorney-general, or, in his absence, the solicitor-general, has a right *ex officio* to file a criminal information in respect of any misdemeanour, but not for treason, felonies or misprision of treason. It is, however, seldom exercised, except in cases which might be described as "enormous misdemeanours," such as those peculiarly tending to disturb or endanger the king's government, e.g., seditions, obstructing the king's officers in the execution of their duties, etc.

There are informations also which are the first step in proceedings in permits of summary jurisdiction leading to the issue of

summonses or warrants. They relate to proceedings of a criminal nature as opposed to complaints which are the initiatory steps to proceedings of a civil nature in these courts.

Civil informations are of two kinds and are filed on the Revenue side of the King's Bench Division. The Latin information is the way in which the Crown recovers money or other chattels, and these informations are either *in rem* or *in personam*. Informations *in rem* are used chiefly where the Crown lays a claim to property and are usually resorted to where such property is alleged to have become forfeited under customs or inland revenue statutes. Informations *in personam* are largely used to recover a debt to the Crown whether such debt is payable by penalty or in another way. The other form of civil information is the English information and is generally used to recover corporeal or incorporeal hereditaments and also debts to the Crown where discovery and an account are sought.

In the United States the Federal Constitution (Amendments Art. V.) forbids the use of informations by providing that "no person shall be held to answer for a capital or otherwise infamous crime, unless on presentment or indictment of a grand jury" with certain exceptions in the land or naval forces and the militia. Attempts at evasion of the revenue laws and other minor offences are sometimes prosecuted by information in the Federal courts. In a number of States all misdemeanours except misprision of treason may be prosecuted by information. This process may also be used in civil cases, such as a proceeding against a corporation for violation of charter.

INFORMER, the term applied to a person who prosecutes in any of the courts of law those who break any law or penal statute, without any direct injury having been done to himself. Such a person is called a common informer when he furnishes evidence on criminal trials or prosecutes for breaches of penal laws solely for the purpose of obtaining the penalty recovered, or a share of it. An action by a common informer is termed a *popular* or *qui tam* action, because it is brought by a person *qui tam pro domino rege quam pro se ipso sequitur*. A suit by an informer must be brought within a year of the offence, unless a specific time is prescribed by the statute. The term informer is also used of an accomplice in crime who turns what is called "king's evidence," or "State's evidence" in the United States (see ACCOMPLICE). In Scotland, informer is the term applied to the party who, in criminal proceedings, sets the lord advocate in motion.

INFUSORIA, a name for the group of single-celled animals (Protozoa) usually called Ciliata, and distinguished by numerous, hair-like, protoplasmic processes (so-called *cilia*), which are used in locomotion and function like oars. The Infusoria are also peculiar in having two different kinds of nuclei (macronuclei and micronuclei), and a peculiar modification of the process of conjugation. (See PROTOZOA.)

INGE, WILLIAM RALPH (1860–), English divine, was born June 6, 1860, at Crayke, Yorks., the son of William Inge, sometime provost of Worcester college, Oxford, and was educated at Eton, and at King's college, Cambridge. From 1884 to 1888 he was a master at Eton, and during the last two years of that time was fellow of King's college, Cambridge. From 1889 to 1904 he was fellow of Hertford college, Oxford. Bampton lecturer in 1899, and Paddock lecturer in New York in 1906, from 1905 to 1907 he was vicar of All Saints', Ennismore Gardens, London, and in 1907 was made Lady Margaret professor of divinity at Cambridge. In 1911 he became dean of St. Paul's, where his sermons attracted great attention owing to their originality, their caustic criticism of the tendencies of modern life and a somewhat pessimistic tone which earned for him the sobriquet of "the gloomy dean."

Among Inge's numerous works may be mentioned *Society in Rome under the Caesars* (1888); *Christian Mysticism* (1899); *Types of Christian Saintliness* (1915); *Philosophy of Plotinus* (1918); *Outspoken Essays* (1919, Second Series 1922); *Personal Religion and the Life of Devotion* (1924); *The Church in the World: Collected Essays* (1928).

INGEBORG (INGEBURGE, INGELBURGE, INGELBORG, ISEMBURGE, Dan. INGIBJÖRG) (c. 1176–1237 or 1238), queen of France, was the daughter of Valdemar I., king of Denmark. She married

in 1193 Philip II. Augustus, king of France, but on the day after his marriage the king took a sudden aversion to her. The council of Compiègne acceded (Nov. 5, 1193) to his demand for a declaration of nullity, but the popes Celestine III. and Innocent III. successively took up the defence of Ingeborg. Philip, having married Agnes of Meran in June 1196, was excommunicated, and as he remained obdurate, the kingdom was placed under an interdict. Agnes was finally sent away, but Ingeborg was shut up in the château of Étampes until, in 1213, Philip, hoping perhaps to justify by his wife's claims his pretensions to England, was reconciled with her. She survived him more than fourteen years, passing the greater part of the time in the priory of St. Jean at Corbeil, which she had founded.

See Robt. Davidsohn, *Philip II. August von Frankreich und Ingeborg* (Stuttgart, 1888); and E. Michael, "Zur Geschichte der Königin Ingeborg" in the *Zeitschrift für Katholische Theologie* (1890).

INGELHEIM (Ober-Ingelheim and Nieder-Ingelheim), the name of two contiguous market-towns of Germany, in the republic of Hesse, on the Selz, near its confluence with the Rhine, 9 m. W.S.W. of Mainz on the railway to Coblenz. Ober-Ingelheim, formerly an imperial town, is still surrounded by walls. Its chief industry is the manufacture of red wine. Pop. (1925) 3,680. Nieder-Ingelheim has in addition to wine, manufactories of machinery, chemicals, malt and limestone quarries. Pop. (1925) 4,438.

Nieder-Ingelheim is, according to one tradition, the birthplace of Charlemagne, and it possesses the ruins of an old palace built by that emperor between 768 and 774.

INGELOW, JEAN (1820-1897), English poet and novelist, was born at Boston, Lincolns., on March 17, 1820, and died in London on July 20, 1897. Jean Ingelow, who was the daughter of a Boston banker, is famous for one poem, "High Tide on the Coast of Lincolnshire"; many of her ballads and songs were set to music in the '70s and had a great vogue. Her works include *Poems* (1863); *The Story of Doom and other Poems* (1867); *Poems* (1885); several novels, of which *Sarah de Berenger* (1880) is perhaps the best known, and a number of excellent children's books, including *Mopsa the Fairy* (1869).

INGEMANN, BERNHARD SEVERIN (1789-1862), Danish poet and novelist, was born at Torkildstrup, Falster, on May 28, 1789. He was educated at the grammar school at Slagelse, and entered the University of Copenhagen in 1806. All his early and unpublished writings were destroyed when the English burned the town. In 1811 he published his first volume of poems, and in 1812 his second, followed in 1813 by a book of lyrics entitled *Procne* and in 1814 the verse romance, *The Black Knights*. In 1815 he published two tragedies, *Masaniello* and *Blanca*, followed by *The Voice in the Desert*, *The Shepherd of Tolosa*, and other romantic plays. In 1818 he went to Rome, where he wrote *The Liberation of Tasso*. In 1820 he began to display his real power in a volume of delightful tales. His last comedy, *Magnetism in a Barber's Shop*, appeared in 1821. In 1822 the poet was nominated lector in Danish language and literature at Sorø college, and in 1846 director. *Valdemar the Great and his Men*, an historical epic, appeared in 1824. The next few years were occupied with his best and most durable work, his four great national and historical novels of *Valdemar Seier* (1826); *Erik Menved's Childhood* (1828); *King Erik* (1833); and *Prince Otto of Denmark* (1835). He then returned to epic poetry in *Queen Margaret* (1836) and in a cycle of romances, *Holger Danske* (1837). His last publication was *The Apple of Gold* (1856). Ingemann died on Feb. 24, 1862. During his lifetime he enjoyed a popularity unapproached even by that of Öhlenschläger.

Ingemann's works were collected in 41 vols. at Copenhagen (1843-1865). His autobiography was edited by Galskjöt in 1862; his correspondence by V. Heise (1879-81); and his letters to Grundtvig by S. Grundtvig (1882). See also H. Schwanenflügel, *Ingemanns Liv og Digting* (1886); and Georg Brandes, *Essays* (1889).

INGERSOLL, ROBERT GREEN (1833-1899), American lawyer and lecturer, was born in Dresden (N.Y.), Aug. 11, 1833. His father was a Congregational minister, who removed to Wisconsin in 1843 and to Illinois in 1845. Robert Ingersoll was admitted to the bar in 1854, and practised law with success in

Illinois. During the Civil War he organized a cavalry regiment, of which he was colonel, until captured at Lexington (Tenn.), Dec. 18, 1862, by the Confederate cavalry under Gen. N. B. Forrest. He was paroled, waited in vain to be exchanged, and in June 1863 resigned from the service. He was attorney-general of Illinois in 1867-69, and in 1876 his speech in the Republican national convention, naming James G. Blaine for the presidential candidate, won him a national reputation as a public speaker. As a lawyer he distinguished himself particularly as counsel for the defendants in the "Star-Route Fraud" trials. He was most widely known, however, for his public lectures attacking the Bible, and his anti-Christian views were an obstacle to his political advancement. Ingersoll was an eloquent rhetorician rather than a logical reasoner. He died at Dobbs Ferry (N.Y.), July 21, 1899.

His principal lectures and speeches were published under the titles: *The Gods and Other Lectures* (1876); *Some Mistakes of Moses* (1879); *Prose Poems* (1884); *Great Speeches* (1887). His lectures, entitled "The Bible," "Ghosts," and "Foundations of Faith," attracted particular attention. His complete works were published in 12 vols. in New York in 1900.

INGERSOLL, a town and port of entry of Oxford county, Ontario, Canada, 19 m. E. of London, on the river Thames and the Canadian National and Canadian Pacific railways. Pop. (1921) 5,150. The principal manufactures are agricultural implements, furniture, pianos and screws. There is a large export trade in cheese and farm produce.

INGHIRAMI, the name of an Italian noble family of Volterra. The following are its most important members:

TOMMASO INGHIRAMI (1470-1516), a humanist, is best known for his Latin orations, seven of which were published in 1777. His success in the part of Phaedra in a presentation of Seneca's *Hippolytus* (or *Phaedra*) led to his being generally known as *Fedra*. He received high honours from Alexander VI., Leo X. and Maximilian I.

FRANCESCO INGHIRAMI (1772-1846), a distinguished archaeologist, fought in the French wars (1799), and afterwards devoted himself especially to the study of Etruscan antiquities. He founded a college at Fiesole and collected a mass of valuable material in his *Monumenti etruschi* (10 vols., 1820-27), *Galleria America* (3 vols., 1829-51), *Pitture di vasi fittili* (1831-37), *Museo etrusco chiusino* (2 vols., 1833), and the incomplete *Storia della Toscana* (1841-45).

His brother, GIOVANNI INGHIRAMI (1779-1851), was an astronomer of repute. He was professor of astronomy at the Institute founded by Ximenes in Florence and published *Effemeridi dell' occultazione delle piccole stelle sotto la luna* (1809-30); *Effemeridi di Venese e Giove all' uso de' naviganti* (1821-24); *Tavole astronomiche universali portatili* (1811); *Base trigonometrica misurata in Toscana* (1818); *Carta topografica e geometrica della Toscana* (1830).

INGLEBY, CLEMENT MANSFIELD (1823-1886), English Shakespearian scholar, was born at Edgbaston, Birmingham, on Oct. 29, 1823, studied at Trinity college, Cambridge, and eventually became partner in the business of his father, a solicitor. But in 1859 he came to London, commenced journalism, and from 1874 devoted himself exclusively to work on Shakespeare. Ingleby exposed the manipulations of J. P. Collier as early as 1859 in his *The Shakespeare Fabrications*. He was at one time vice-president of the New Shakspeare Society, and was one of the original trustees of the "birthplace." His other works include: *Shakespeare Hermeneutics* (1875); *Shakespeare: The Man and the Book* (1877-81); and *Shakespeare's Bones* (1882), in which he recommended disinterment and examination of Shakespeare's skull.

INGLEFIELD, SIR EDWARD AUGUSTUS (1820-1894), British admiral and explorer, was born at Cheltenham, on March 27, 1820, and educated at the Royal Naval College, Portsmouth. The boy went to sea at fourteen, saw service on the Syrian Coast in 1840, and in 1845 was promoted commander for gallant conduct at Obligado. In 1854 he was sent out on the Admiralty's last attempt to find Sir John Franklin. In the Crimean War Captain Inglefield took part in the siege of Sevastopol. He was promoted admiral in 1877. Besides being an ex-

cellent marine artist, he invented the hydraulic steering gear and the Inglefield anchor. He died on Sept. 5, 1894.

INGLE NOOK, originally the corners of a large fire-place, under the main chimney-breast opening, and on either side of the spot where the fire was built. In many Tudor, Jacobean and early American fire-places there is sufficient width and depth to place a wooden bench or settle on each side, within the opening. In modern usage, the term is applied more loosely to any recess or alcove containing a fire-place at the end and usually furnished with settles or seats at the sides.

INGLIS, ELSIE MAUD (1864–1917), British physician and surgeon, was born at Naini Tal, India, on Aug. 16, 1864. After a childhood spent in India and Australia, in 1878 she settled with her family in Edinburgh. She studied at the school of medicine for women in Edinburgh, and at St. Margaret's college, Glasgow, graduating M.B. and C.M. In 1895 she took up private practice in Edinburgh and was instrumental in establishing a second school of medicine for women in that city. Dr. Inglis became one of the most prominent suffrage workers in Scotland. She became in 1892 house-surgeon to the New Hospital for Women, London (afterwards the Elizabeth Garrett-Anderson hospital), and later on co-surgeon at an Edinburgh dispensary. She was one of the founders of the Edinburgh hospice for women (est. 1901), at that time the only maternity training centre in Scotland managed by women. She began private practice in Edinburgh in 1895. In Aug. 1914, inspired by her, a special committee of the Scottish Federation of Women's Suffrage Societies, aided by the National Union of Women's Suffrage Societies, undertook the organization of the Scottish women's hospitals for foreign service, and raised £449,000. She first went to Serbia in April 1915 to relieve Dr. Soltau at Kragujevac. In November, during the enemy invasion of Serbia, Dr. Inglis and a few others remained behind until Feb. 1916 as prisoners of the enemy to care for the Serbian wounded. In Aug. 1916 she took a unit to the Dobruja for service with the newly-formed Serbian division attached to the Russian army. She was seriously enfeebled by the hardships endured, and died (Nov. 26, 1917) the day after landing in England.

See Lady Frances Balfour, *Dr. Elsie Inglis* (1918); and Mrs. Shaw McLaren, *Elsie Inglis* (1920).

INGLIS, SIR JOHN EARDLEY WILMOT (1814–1862), British major-general, son of John Inglis, third bishop of Nova Scotia, was born in Nova Scotia on Nov. 15, 1814. In 1833 he joined the 32nd Foot, in which all his regimental service was passed. In 1837 he saw active service in Canada and in the Punjab (1848–49), being in command at the storming of Mooltan and at the battle of Gujarat. In 1857, on the outbreak of the Indian Mutiny, he was in command of his regiment at Lucknow. Sir Henry Lawrence being mortally wounded during the siege of the residency, Inglis continued the defence for 87 days against an overwhelming force. He was promoted to major-general and made K.C.B. He was, in 1860, given command of the British troops in the Ionian Islands. He died at Hamburg on Sept. 27, 1862.

INGLIS, SIR WILLIAM (1764–1835), British general, born in 1764, entered the army in 1781. After ten years in America he served in Flanders, taking part in the capture of St. Lucia. In 1809 he commanded a brigade in the Peninsula, taking part in the battle of Busaco (1810) and the first siege of Badajoz. At Albuera his regiment, the 57th, occupied a most important position, exposed to a deadly fire. "Die hard! Fifty-seventh," cried Inglis, "Die hard!" The regiment's answer has gone down to history. Out of a total strength of 579, 23 officers and 415 rank and file were killed and wounded. Inglis himself was wounded. On recovering, he saw further Peninsular service. He died at Ramsgate on Nov. 29, 1835.

INGOLSTADT, a town of Germany, in the republic of Bavaria, on the left bank of the Danube at its confluence with the Schutter, 52 m. N. of Munich, at the junction of the main lines of railway, Munich, Bamberg and Regensburg-Augsburg. Pop. (1925) 26,630. Ingolstadt, known as *Aureatum* or *Chrysopolis*, was a royal villa in the beginning of the 9th century, and received

its charter of civic incorporation before 1255, and later became the capital of a dukedom which merged in that of Bavaria-Munich. The fortifications were erected in 1539. In 1800 the French, under General Moreau, took the town, and dismantled the fortifications. They were rebuilt on a much larger scale under King Louis I., and after 1870 Ingolstadt ranked as an important fortress. The principal buildings are the old palace of the dukes of Bavaria-Ingolstadt; the remains of the earliest Jesuits' college in Germany, founded in 1555; the former university buildings, now a school; and the large Gothic Frauenkirche, founded in 1425, with two massive towers, containing the tomb of Dr. Eck, Luther's opponent. In 1472 a university was founded in the town by the Bavarian duke, Louis the Rich, which at the end of the 16th century was attended by 4,000 students. In 1800 it was removed to Landshut, whence it was transferred to Munich in 1826. The industries are metal founding and the manufacture of locomotives and machinery.

INGOT, originally a mould for the casting of metals, but now a mass of metal cast in a mould, and particularly the small bars of the precious metals, cast in the shape of an oblong brick or wedge with slightly sloping sides, in which form gold and silver are handled as bullion at the Bank of England and the Mint. Ingots of varying sizes and shapes are cast of other metals, and "ingot-steel" and "ingot-iron" are technical terms in the manufacture of iron and steel (see IRON AND STEEL).

INGRAM, ARTHUR FOLEY WINNINGTON (1858–), English divine, was born in Worcestershire on Jan. 26, 1858, and educated at Marlborough College, and Keble College, Oxford. His first curacy was at St. Mary's, Shrewsbury, in 1884; in 1885 he became private chaplain to the Bishop of Lichfield and in 1889 head of the Oxford House, Bethnal Green, where he became much loved for his devoted work among the poor. In 1897 he was appointed suffragan bishop of Stepney, which carried with it a canonry in St. Paul's. In 1901, after the death of Dr. Mandell Creighton, he was nominated by the Crown to the see of London. The appointment, which had hitherto been reserved for men who had made their mark as scholars and administration rather than in pastoral work, excited much comment; but it was undoubtedly popular. As a preacher Dr. Ingram attracted great audiences. During the World War he threw himself into the work of providing religious instructions for the fighting men, visiting both the French front and the Grand Fleet. He went on a world tour in July 1926, returning in May 1927. He visited several Canadian towns and delivered an address at the centenary celebration of the foundation of Ottawa. Dr. Ingram also took a prominent part in the discussions on the proposals for the revision of the Prayer-book in 1927 and 1928.

INGRAM, JAMES (1774–1850), English antiquarian and Anglo-Saxon scholar, was born near Salisbury on Dec. 21, 1774. From 1803 to 1808 he was professor of Anglo-Saxon at Oxford, and in 1824 was made president of Trinity college and D.D. He was the pre-eminent Anglo-Saxon scholar of his time. He died on Sept. 5, 1850. He published an edition of the *Saxon Chronicle* (1823), *Memorials of Oxford* (1832–37); and *The Church in the Middle Centuries* (1842).

INGRAM, JOHN KELLS (1823–1907), Irish scholar and economist, was born in Co. Donegal, Ireland, on July 7, 1823, and educated at Newry school and Trinity college, Dublin. Elected fellow of his college in 1846, he became successively professor of oratory and English literature (1852–66), regius professor of Greek (1866), and librarian (1879). Always remarkable for his versatility, he made a reputation in the fields of literature, philosophy and science, as well as political economy. He contributed an historical and biographical article on economics to the 9th edition of the *Encyclopædia Britannica* which was translated into many European languages. He died in Dublin on May 18, 1907. His principle works are *Greek and Latin Etymology in England*; *The Etymology of Liddell and Scott*; *The Outlines of the History of Religion* (1900); *Human Nature and Morals According to A. Comte* (1901); *Practical Morals* (1904); *The Final Transition* (1905); and *Sonnets and Other Poems* (1900).

INGRES, JEAN AUGUSTE DOMINIQUE (1780–1867), French painter, was born at Montauban, on Aug. 29, 1780. His father has described himself as *sculpteur en plâtre*. In consequence of the son's talent for music—the lad's performance of a concerto of Viotti's was applauded at the theatre of Toulouse—his father at first wished him to take up music. At Toulouse, whither his father had removed from Montauban in 1792, Ingres received lessons from Joseph Roques, from Vigan, professor at the academy of fine arts, and from Briant, a landscape-painter. The sight of a copy of Raphael's "Madonna della Sedia" came to him as a revelation and confirmed him in his desire to become a painter.

He started for Paris about the close of 1796. He was admitted to the studio of David, for whose lofty standard and severe principles he always retained a profound appreciation. Ingres, after four years of devoted study, during which (1800) he obtained the second place in the yearly competition, finally carried off the Grand Prix (1801). The work thus rewarded—the "Ambassadors of Agamemnon in the Tent of Achilles" (École des Beaux Arts)—was much admired by Flaxman. In 1804 Ingres exhibited "Portrait of the First Consul" (Musée de Liège), and portraits of his father and himself (Musée Ingres and Chantilly); these were followed in 1806 by "Portrait of the Emperor" (Invalides), and portraits of Mme. and Mlle. Rivière (Louvre). It was not until 1806 that the state of public affairs admitted of the re-establishment of the Academy of France at Rome. The first year in Rome Ingres produced the portraits of Granet (Musée Aix) and of Madame Devauçay (Musée Chantilly). In 1808 followed "Oedipus and the Sphinx" and the "Grande Baigneuse" (both in the Louvre). These works were followed by some of his best portraits, that of M. Bochet (Louvre), and that of Mme. la Comtesse de Tournon; in 1811 he finished "Jupiter and Thetis," an immense canvas now in the Museum of Aix, and in 1812 "Romulus and Acron" (École des Beaux Arts). "Don Pedro of Toledo Kissing the Sword of Henry IV." (Collection Deymié; Montauban) was exhibited at the Salon of 1814, together with the "Chapelle Sistine" (Collection Madame Pougin de la Maisonnette) and the "Grande Odalisque" (Louvre). In 1813 Ingres executed "Raphael and the Fornarina" (Museum of Riga).

During all these years Ingres's reputation in France did not increase. The interest which his "Chapelle Sistine" had aroused at the Salon of 1814 soon died away; amongst his brother artists Ingres found scant recognition. The strict classicists looked upon him as a renegade, and strangely enough Delacroix and other pupils of Guérin—the leaders of that romantic movement for which Ingres, throughout his long life, always expressed the deepest abhorrence—alone seem to have been sensible of his merits. The weight of poverty, too, was hard to bear. In 1813 Ingres had married Madeleine Chapelle, who speedily acquired a faith in her husband which enabled her to combat the difficulties which beset their existence, and which were increased by their removal to Florence.

The good offices of his friend Bartolini, and of one or two other persons, could only alleviate the miseries of this stay in a town where Ingres was all but deprived of the means of gaining daily bread by the making of those small portraits for the execution of which, in Rome, his pencil had been constantly in request. Before his departure he had, however, been commissioned to paint for de Pastoret the "Entry of Charles V. into Paris," and de Pastoret now obtained an order for Ingres from the Administration of Fine Arts; he was directed to treat the "Voeu de Louis XIII." for the cathedral of Montauban. This work, exhibited at the Salon of 1824, met with universal approbation. On his return Ingres was received at Montauban with enthusiastic homage, and found himself celebrated throughout France.

In the following year (1825) he was elected to the Institute, and his fame was further extended in 1826 by the publication of Sudre's lithograph of the "Grande Odalisque," which, having been scorned by artists and critics alike in 1819, now became widely popular. A second commission from the government called forth the "Apotheosis of Homer" (Louvre), originally meant for a ceiling decoration. One of the finest portraits of this period is

that of "Bertinainé" (Louvre). From this date up till 1834 the studio of Ingres was thronged. Whilst he taught with despotic authority and admirable wisdom, he steadily worked; and when in 1834 he produced his great canvas of the "Martyrdom of Saint Symphorien" (cathedral of Autun), it was with angry disgust and resentment that he found his work received with the same doubt and indifference as had met his earlier ventures.

Ingres gladly availed himself of the opportunity to return to Rome, as director of the École de France, in the room of Horace Vernet. There he executed "La Vierge à l'Hostie" (Leningrad), "Stratonice" (Mus. Chantilly), "Portrait of Cherubini" (Louvre) and the "Petite Odalisque" (Coll. Gust. Pereire). The "Stratonice," executed for the duke of Orleans, had been exhibited at the Palais Royal for several days after its arrival in France, and the beauty of the composition produced so favourable an impression that, on his return to Paris in 1841, Ingres found himself received with deference. A portrait of the duke of Orleans (Mus. Versailles) was one of the first works executed after his return. In 1845 he painted Madame d'Haussonville (Château Coppet), one of his best female portraits; shortly afterwards he began the decorations of the great hall in the Château de Dampierre, which were begun with an ardour which gradually slackened, until in 1849 Ingres abandoned all hope of their completion, and the contract with the duc de Luynes was cancelled.

Ingres's next considerable undertaking (1853) was the "Apotheosis of Napoleon I.," painted for the ceiling of a hall in the Hôtel de Ville (destroyed); "Jeanne d'Arc" (Louvre) appeared in 1854; and in 1855 Ingres consented to rescind the resolution, more or less strictly kept since 1834, in favour of the International Exhibition, where a room was reserved for his works. Prince Napoleon, president of the jury, proposed an exceptional recompense for their author, and obtained from the emperor Ingres's nomination as grand officer of the Legion of Honour. With renewed confidence Ingres now took up and completed one of his most charming productions—"La Source" (Louvre). In 1862 Ingres completed "Christ and the Doctors" (Musée Montauban), a work commissioned many years before by Queen Marie Amélie for the chapel of Bizy.

On Jan. 14, 1867, Ingres died in his 88th year, having preserved his faculties in wonderful perfection to the last. In the same year was opened the Musée Ingres at Montauban, which contains the greatest collection of his paintings and drawings and constitutes a fine memorial to the artist. His art was wholly based on form and line. Except in his "Sistine Chapel," and one or two slighter pieces, Ingres kept himself free from any preoccupation as to depth and force of colour and tone; driven, probably by the excesses of the Romantic movement, into an attitude of stricter protest, "ce que l'on sait" he would repeat, "il faut le savoir l'épée à la main." His admiration for Raphael inspired the remark, "*Je suis donc un conservateur des bonnes doctrines et non un novateur.*" His constant and keen study of nature, however, prevented his becoming an eclectic, and we find him at his best whenever he worked from nature. It is not by his wonderful portraiture alone that his art will live. His drawings are cherished by all lovers of art and his picture the "Grande Odalisque" ranks as one of the finest interpretations of the nude. He had many pupils; the most important was Chassériau; but his influence extended beyond his class and is felt in modern painting. He was worshipped by Gauguin, Puvis, Degas; and the cubists claim him as a kindred spirit.

See H. Lapauze, *Ingres, sa Vie et son Oeuvre* (1911).

INGRESS, entrance as opposed to exit or egress; in astronomy, the apparent entrance of a smaller body upon the disc of a larger one, as it passes between the latter and the observer; in this sense it is applied especially to the beginning of a transit of a satellite of Jupiter over the disc of the planet.

INGUSHETIA, an autonomous area created in July, 1924, within the North Caucasian Area, occupying 3,199 sq.km. The watershed of the Caucasus forms its southern boundary, where Georgia borders it, the Kabardian territory lies to the north, the Chechen to the east and the North Ossetian to the west. The mountain region consists of the peaks, ridges and deep ravines of

the main crest of the Caucasus lying east of Kazbek; the lowland is the eastern extension of the Vladikavkaz valley, and merges into the Kabardian plain. This small lowland area is only 200 metres above sea level, but much of Ingushetia is 4,000 metres, with scattered peaks rising even higher. It is drained by the Terek and its tributaries the Armkhi, Sunzha, Kambileyevka; the Ossa river, a tributary of the Sunzha, is the main stream in the district. The climate varies with the relief; the annual rainfall may be 500 to 840 mm., and is greatest from the end of spring to midsummer, with a further fall at the beginning of winter. This type of rainfall favours the growth of maize, but is bad for wheat. There are seven meteorological stations in Ingushetia which record average January temperature -4.5° to -5.4° C and July 20.6° to 22.2° C. The temperature is rarely higher than 22.6° C. The north of the valley of the Armkhi, on the Stolovoi slopes, is, however, practically rainless and the hill meadows are parched in summer, while the south below the snow-line is covered with mixed pine and deciduous forest where health resorts could be favourably developed. Near Kabardia the climate approximates to the dry continental type of the North Caucasian Area, and the soil is a transition type between chestnut coloured and black earth (see RUSSIA, *Soils*); typical steppe vegetation is found here. On the southern slopes of the hills are forests of ash, lime, oak, wild cherry and a great variety of shrubs; on the northern are birch and willow. In the Black mountain region, beech occupies 70% of the forest, the rest being lime, hazel, oak, apple and pear. On the higher slopes are pine forests and alpine and sub-alpine meadows. Agriculture is the chief occupation; there are no settlements large enough to be called towns, the administrative offices are in Vladikavkaz. The cultivation of maize occupies the first place in the local economy; in 1926, of 50,800 hectares of cultivated land 97.4% were under maize. Livestock breeding, mainly of a nomad type relying on pasturage, supplemented in the winter by maize forage, comes next. In 1926 there were roughly 55,000 sheep, 52,000 working cattle, 21,600 horses and 5,500 goats, *i.e.*, about 75% of the number in 1913. Potatoes, vegetables, fruit, melons and cucumbers are grown and could be profitably developed for the market if transport facilities were provided. Beekeeping forms a supplementary occupation. The tiny scattered hamlets in the higher valleys rely almost exclusively on their flocks of sheep, goats and chamois which provide them with wool for homespun and with leather, meat and milk. The Ingushetes in these regions are wild and lawless; the blood feud is common and trade is of an exchange and barter type. Their homes are smoky, windowless hovels, and eye diseases are common. The valley Ingushetes are settled cultivators and their easier contact with their Russian neighbours has considerably modified their customs. The absence of transport facilities is marked, roads are non-existent in many places, and the hill streams are impossible for navigation. Only 7 km. of the westward railway from Grozny comes into the area, with Nazran as its stopping place. Until communications have improved, the timber wealth of the region will remain unexploited; at present it has not been surveyed completely. Nor, as yet, has a geological survey been completed. A westward extension of the Grozny naphtha beds exists in the Achalukov region, in which also copper and sulphur pyrites are known to exist, but they are not worked. It is estimated that there must also be layers of copper, asbestos, coal and saltpetre in other regions. Mineral springs exist, and those at Achaluk are much resorted to by the native tribes. At present, the only mining activity is carried on by peasant *artels* working salt, lime and ochre. There are two factories which export products outside Ingushetia, one a brandy distillery, and the other a starch factory. According to the 1926 census the population was roughly 75,200, of whom more than 90% were Ingushetes. The literacy rate is about 6% for men and less than 1% for women. Education in a hill community with poor communications and a slender budget presents great difficulties; the number of primary schools in 1925-6 was 22, and there were 1,260 scholars; it is evident that in such circumstances the rate of literacy cannot increase rapidly. Health services are poor; there is one hospital, with 20 beds, for the whole area. Government stations for dealing with malaria,

tuberculosis and social diseases have recently been established. The Ingushete language is closely allied to that of the Chechens, and both Ingushetians and Chechens call themselves "nakhchi" (people). The Ingushetes also call themselves "Lamur," "Galgai" or "Nazranovs." In physical type they are extremely varied, and dark brown, blue and light grey eyes are common; the prevailing hair shades are dark red and black, and a large proportion is dolichocephalic.

In 1926 an Ingushetian Research Institute was founded in Vladikavkaz. The district is full of interest because it has preserved its ancient customs to so late a date. Numerous cist burials, associated with Bronze and Iron cultures, have been discovered, some crouched and some extended, but all with the head oriented to the west. Until the middle of the 19th century burials took place in "kashi," or two storied chambers, some hut-shaped with pyramidal roofs and some cone shaped. The corpses were piled up to the ceiling buried in their ordinary garments, and with utensils and weapons for use in the next world. These sepulchres were built of stone cemented with clay or lime and were whitewashed on the outside; the window was to the east and the roof of the lower chamber vaulted, with a window in the north leading to the upper chamber. Owing to the dryness of the atmosphere, the corpses became partially mummified. A marked feature of Ingushete "auls" or mountain villages from the 15th century to modern times is the erection of military and residential turrets, mostly square at the base and tapering towards the top: the military turrets are often 70 ft. high with 4 or 5 storeys. They are an indication of the state of perpetual tribal warfare existing in the region. In the 11th century the Ingushetes were dependent on Georgia, but in the early 15th century the Kabardians conquered them and exacted tribute so oppressively that the Ingushetes placed themselves under Russian protection in 1770. The Kabardians resented this and a Russian regiment under General Medemom was sent to pacify the district. From that time onwards sporadic outbreaks of unrest continued, in which religious fanaticism played its part. The Ingushetes are Mohammedans of the Sunni sect, and joined the rebellion under Shamil (*q.v.*). The building of the Georgian military road, the establishment of Cossack military outposts and finally the building of the railway to Vladikavkaz gradually pacified the district, but the bands of Ingushete highway robbers, retreating to their inaccessible mountain fastnesses, have been a thorn in the side of settled government.

See N. Yakovlev, *Ingushi* (Moscow, 1925).

INHAMBANE, a seaport of Portuguese East Africa, in $23^{\circ} 50'$ S., $35^{\circ} 25'$ E., 280 m. from Beira and 248 from Delagoa bay. It is situated on a river of the same name which enters Inhambane bay. In 1921 the maximum temperature was 90° and the minimum 58° . The town dates from the middle of the 16th century. The principal church is built with stone and marble brought from Portugal. A water supply and the electric light have recently been installed. Trade was formerly mostly in ivory and slaves. In 1834 Inhambane was taken by a Zulu horde under Manukosi (see GAZALAND). It was not until towards the close of the 19th century that the trade of the town revived. In 1926, 160 tons of mafurra, 200 tons of copra, and 490 tons of sugar were exported among other products. Cotton goods and cheap wines (for consumption by natives) are the principal imports. The harbour is about 9 m. long by 5 wide. The bar and channels are marked by illuminated buoys. The depth of water over the bar varies from 17 to 28 ft. The port has a ferro-concrete wharf, 379 ft. long, at which large steamers can berth. The depth at low spring tides is 23 ft. In 1925-6, 103 ships left the port with 352,280 tons of cargo. Goods landed amounted to 71,138 tons.

Inhambane is the natural port for the extensive and fertile district between the Limpopo and Sabie rivers. This region is the best recruiting ground for labourers in the Rand gold mines. Mineral oils have been found within a short distance of the port. The town has official primary schools. Trade schools have been established in nearly all the circumscriptions of the district. There is a wireless station with a range of 300 miles.

See *Delagoa Bay Directory* (1927).

INHERITANCE. In English law the heir is simply the person on whom the real property of the deceased devolved by operation of law if he died intestate (*see* HEIRS). Until 1926 the devolution of an inheritance in England was regulated by the rules of descent, as altered by the Inheritance Act 1833, amended by the Law of Property Amendment Act 1859.

1. The first rule was that inheritance shall descend to the issue of the last "purchaser." A purchaser in law means one who acquires an estate otherwise than by descent, *e.g.*, by will, by gratuitous gift or by purchase in the ordinary meaning of the word. Under the earlier law descent was traced from the last person who had "seisin" or feudal possession. 2. The male was admitted before the female. 3. Among males of equal degree in consanguinity to the purchaser, the elder excluded the younger; but females of the same degree took together as "coparceners." 4. Lineal descendants took the place of their ancestor. 5. If there were no lineal descendants of the purchaser, the next to inherit was his nearest lineal ancestor. 6. The sixth rule was thus expressed by Joshua Williams in his treatise on *The Law of Real Property*:—

The father and all the male paternal ancestors of the purchaser and their descendants shall be admitted before any of the female paternal ancestors or their heirs; all the female paternal ancestors and their heirs before the mother or any of the maternal ancestors or her or their descendants; and the mother and all the male maternal ancestors and her and their descendants before any of the female maternal ancestors or their heirs.

7. Kinsmen of the half-blood might be heirs; such kinsmen shall inherit next after a kinsman in the same degree of the whole blood, and after the issue of such kinsman where the common ancestor is a male and next after the common ancestor where such ancestor is a female. 8. In the admission of female paternal ancestors, the mother of the more remote male paternal ancestor and her heirs were preferred to the mother of the less remote male paternal ancestor and her heirs; and, in the case of female maternal ancestors, the mother of the more remote male maternal ancestor was preferred to the mother of a less remote male maternal ancestor. Failing heirs of all kinds, the lands of an intestate purchaser, not alienated by him, would revert by "escheat" (*q.v.*) to the next immediate lord of the fee, who would generally be the crown.

By s. 45 of the Administration of Estates Act 1925, all existing modes, rules and canons of descent were abolished and new rules were substituted. (*See* INTESTACY.)

Scotland.—In Scotland the rules of descent differ from the above in several particulars. Descent is traced, as in England before the Inheritance Act, to the person last seized. The first to succeed are the lineal descendants of the deceased, and the rules of primogeniture, preference of males to females, equal succession of females (heirs-portioners), and representation of ancestors are generally the same as in English law. Next to the lineal descendants, and failing them, come the brothers and sisters, and their issue as collaterals. Failing collaterals, the inheritance ascends to the father and his relations, to the entire exclusion of the mother and her relations. Even when the estate has descended from mother to son, it can never revert to the maternal line. As to succession of brothers, a distinction must be taken between an estate of heritage and an estate of conquest. Conquest is where the deceased has acquired the land otherwise than as heir, and corresponds to the English term purchase in the technical sense explained. Heritage is land acquired by deceased as heir. The distinction is important only in the case when the heir of the deceased is to be sought among his brothers; when the descent is lineal, conquest and heritage go to the same person. And when the brothers are younger than the deceased, both conquest and heritage go to the brother (or his issue) next in order of age. But when the deceased leaves an elder and a younger brother (or their issues), the elder brother takes the conquest, the younger takes the heritage. Again, when there are several elder brothers, the one next in age to the deceased takes the conquest before the more remote, and when there are several younger brothers, the one next to the deceased takes the heritage before the more remote. When heritage of the deceased goes to an elder brother (as might

happen in certain eventualities), the younger of the elder brothers is preferred.

The position of the father, after the brothers and sisters of the deceased, will be noticed as an important point of difference from the English axioms; so also is the total exclusion of the mother and the maternal line. As between brothers and sisters the half-blood only succeeds after the full blood. Half-blood is either consanguinean, as between children by the same father, or uterine, as between children having the same mother. The half-blood uterine is excluded altogether. Half-blood consanguinean succeeds thus: if the issue is by a former marriage, the youngest brother (being nearest to the deceased of the consanguinean) succeeds first; if by a later marriage than that from which the deceased has sprung, the eldest succeeds first.

In many of the British dominions and colonies the English law of inheritance has been greatly modified by legislation.

(W. A. B.)

United States.—American law borrowed its rules of descent of real estate considerably more from the civil law than the common law. "The 118 novel of Justinian has a striking resemblance to American law in giving the succession of estates to all legitimate children without distinction and disregarding all considerations of primogeniture. There is one particular in which the American law differs from that of Justinian, that while generally in the United States lineal descendants if they stand in an equal degree from the common ancestor share equally *per capita*; under the Roman law regard was had to the right of representation, each lineal branch of descendants taking only the portion which their parent would have taken had he been living, and the division being *per stirpes* and not *per capita*. But in some of the states the rule of the Roman law in this respect has been adopted and retained." When such lineal descendants stand in unequal degrees of consanguinity the inheritance is *per stirpes* and not *per capita* (In re Prote, 1907; 104 N.Y. Supplement 581). This is the rule in practically all the States.

The entire subject of descent has, substantially, become statutory. The principal changes have been in uniformity of rules as between real and personal property and a more substantial provision for the wife. An important feature at common law—"the blood of the ancestor"—is no longer of importance.

But as in no two States are the rules of descent identical, the only safe guides are the statutes and decisions of the particular State in which the property to be inherited is situated. In 41 States the rules for the descent of real and personal property are the same, in seven States they still differ. The law of primogeniture as understood in England is abolished throughout the United States, and male and female relatives inherit equally.

The distinction between relatives of the whole and half blood is not ordinarily in force. In a few States it is abolished by statute. In three States those of full blood are preferred.

The English rule that natural children not subsequently legitimated have no inheritable blood has been greatly modified. In several States inheritable blood exists between a natural child and its mother. In Pennsylvania, this is extended to its maternal grandparents. In Arizona there is no distinction. In some States, a subsequent marriage removes the bar as does recognition by the father in some States. Common law dowers have been largely regulated by statutes which give certain rights to the surviving wife in lieu thereof—usually more favourable to her than her common law dower. In several States she takes a third interest in fee in land alienated by her husband in his lifetime without joining her in the deed—usually one-third; in Kansas one-half interest in fee. Curtesy has likewise been very generally abolished and certain statutory rights given to a surviving husband instead. In the States which came in through the Spanish or French titles, dower and curtesy had no place.

In default of issue and subject to the share of the spouse, the parents usually take, and failing parents, collaterals take. A usual form of statute gives the wife one-half where there is but one child; if there be more than one child, the wife takes a child's share.

Degrees of kindred in the United States generally are com-

puted according to the civil law, *i.e.*, by adding together the number of degrees between each of the two persons whose relationship is to be ascertained and the common ancestor. Thus, relationship between two brothers is in the second degree; between uncle and nephew in the third degree; between cousins, in the fourth, etc. In a few States such degrees are computed according to the common law, *i.e.*, by counting from the common ancestor to the more remote descendant of the two from him—thus, brothers would be related in the first degree, uncle and nephew in the second, etc. In most States representation amongst collaterals is restricted—in some to the descendants of brothers and sisters, in others to their children only.

In eight States (California, Louisiana, Texas, Arizona, Idaho, Nevada, New Mexico and Washington) the law of "community property" of husband and wife prevails. This is derived from the French and Spanish law existing in the territories out of which those States were formed as the result of the Spanish and French occupation. The foundation idea is an equal division at the death of either party of all property acquired during their marriage except by gift, devise or descent. In general the husband has the control and management thereof during the marriage, and the survivor has the administration of the moiety of the one deceased. (F. R.)

INHERITANCE: ECONOMIC ASPECTS. There are no ideas of inheritance which can be shown to be "natural" or absolute, as may well be seen by comparing the ideas prevailing in different countries at the same time, or in the same country at different times. It has been well said "Most Englishmen who have not studied comparative law, will think it natural that the ownership of their property after their death should be governed by their last will and testament. Most Frenchmen, in like case, will think it natural that the operation of their will should be subject to the law of the *légitime*. But many Indians, far from thinking the disposition of property by will to be natural, will find great difficulty in understanding what the mere idea of a will signifies and implies. Indeed, Maine has pointed out that to the vast majority of mankind throughout recorded history the idea would be quite incomprehensible" (H. Dalton, *Inequality of Incomes*).

The rights of Inheritance and Bequest are commonly confused. In general, by an absolute right of bequest is meant the freedom to leave one's possessions exactly as one pleases, whereas an absolute right of inheritance is actually an inalienable right to possess what someone has left according to a rule that commends itself to our sense of natural fitness. An Englishman, finding that his parents have left their wealth to some stranger, may be pardoned for emphasizing moral rights of inheritance. A Frenchman, finding that a substantial part of his hardly accumulated fortune must go, whether he likes it or not, to a son who has, by his conduct, no moral claim upon it, may be excused for discussing the right of bequest. One in either nation who has neither wealth to leave nor to receive, may well be pardoned when he questions the social utility of any system which acts as a conduit pipe for much current production into areas where he has no claim.

Family Inheritance and Incentive to Work.—Much of the philosophy of bequest and inheritance is bound up in the philosophy of private property, and in so far as individuality in the production, as well as the spending and direction of wealth, is for the social good, the right of bequest, it may be argued, is an important attribute of private ownership. But the right to make *family* bequest and the right to make bequest in *any* direction are very different in social importance. It is probable that the incentive to work and to save would be very seriously impaired if family inheritance were not allowable, whereas restrictions in the wider right of general bequest might well exist without untoward social effects.

"The permanence of the family has a social value which the right of inheritance helps to maintain." Similarly "the practice of charitable bequest led at an early date to the recognition by law that there are certain purposes which may well be made more permanent than the lives of the individuals who serve them." It is fairly generally agreed that *some* rights of inheritance, how-

ever limited and controlled, are essential to the full economic advantage of property as a social institution, and the precise degree is a matter relative to the stage of social development.

The philosophical theory that the "mixing" of labour with material, in whatever proportions, constituted a natural right in the material, however valid for the lifetime of the worker, gave little guidance as to the rights of heirs who had not worked upon it, and failed to provide a self-evident principle. Locke thought that liberty of bequest was obvious or natural. The fact that three distinct systems prevailed, even in England, for intestacy, could only be accounted for by assuming that a law of nature had been modified by State-made law, based upon the social contract. But as Hastings Rashdall points out, the obligation to keep the contract rests upon a principle of natural law, and these principles seem to be in conflict. Any system which supports the right of primogeniture must prove to be illogical on a Lockian basis.

Right of Bequest.—Some right of inheritance in practice, but never unconditional rights, are found in the earliest times. In England the laws of inheritance have tended to give way to the absolute right of bequest. The power to dispose of lands by will dates from Henry VIII., and there is now an unlimited power of disposition except for entailed estates, so that there are no rights of wife or children which cannot be set aside. Where the will of the owner has not been actually expressed by him, the rights have differed widely up to 1926 according to whether the property was real or personal estate. The widow had a life interest in one-third, the husband, if there were children, had a life interest in the whole. But under Kentish gavelkind custom, their interests were one-half each, the wife's continuing until remarriage. Under "Borough English" the younger son took preference. The somewhat arbitrary character of succession to land illustrates the absence of "natural" law. Males are preferred to females. Where two or more males with equal relationship are in question, the eldest inherits, but if they are females they take equally. The father, his issue, and his ancestors, however distant, take priority over the mother and her ancestors. "A more remote male ancestor and his issue are excluded by a nearer male ancestor and his issue, but the mother of a more remote male ancestor and her issue are *preferred* to the mother of a nearer male ancestor and her issue. Thus land goes to remote relations on the father's side before it can go to even the mother on the mother's side. "It would be hard to justify the continuance of such rules in a modern civilized country, and it is only the complete freedom of will making which has prevented them from being found intolerable" (Geldart).

In personality, the husband took all his intestate wife's property, but the wife could take only one-third (or one-half if there were no issue). Even if he had no ascertainable relatives the wife was restricted to half, the rest went to the Crown. By a recent legislation (1926) the old rules of intestate succession are repealed, and the principle has been to distribute property much more in accord with what most deceased persons would have adopted if they had made a will. Now the husband (or wife) takes all personal chattels absolutely, £1,000 free of death duty, the whole residue if there are no children, or one-half if there are. The degree of relationship entitled to benefit now goes no further than first cousins and their issue, and the residue goes to the Crown.

There are general restrictions on the power to will property in England, for property may not be left to waste, or accumulate perpetually; nor can a succession of owners be prescribed beyond a period of 21 years after the death of persons alive at his own death. But otherwise the claims of the nearest kin can be almost ignored. The British ideas extend to the dominions and most of the United States, though in the United States a widow is generally entitled to one-third of the personality, and a life interest in one-third of her realty. But on the continent of Europe the *légitime* prevails, when near relatives are secured by definite rights. In France, the right of free bequest extends only to a fraction. In Italy, one-half of the property has followed a settled rule. The French form has narrowed, through the Napoleonic régime, from an earlier form (to which Quebec is still attached) whereas

England (as distinct from Scotland) broadened from narrower ideas.

Ideas upon Limitations of Rights.—If unlimited freedom of inheritance and of bequest are not natural rights, it at once becomes an important question how they may be limited, and in general the test applied is that of "social desirability." But the definition of what is socially desirable has proceeded in the past too much upon distinctions as to abstract justice or fairness, and very little examination has been made, or estimate attempted, of the effects upon production of different practices. Although diffusion of wealth and "better" distribution of wealth have been used as reasons for limitation and legal direction, the economic consequences are not clearly known or distinguished. Thus Jeremy Bentham (1795) wished to abolish intestacy, passing all property to the State, and where wills were made, to limit the powers of those who had no direct heirs. In any case, the State was to have half share of sums going under a will to grandparents, uncles, nephews, and also a reversionary interest in what went to childless heirs. Bentham had the ideas of just taxation most in mind, based on the absence of any natural right of inheritance, and the fact that extensive privileges to collateral relatives were only defensible to a limited extent. Graduation of such a tax according to degree of relationship was a corollary.

J. S. Mill thought the right to make bequest was inherent in the idea of property, but the right to inherit was not. His pleas for limitation of bequest were mostly on ethical grounds, but he was not blind to economic considerations, for he recognized: (a) an economic disadvantage in the past, in letting family property be broken up, and a little commonwealth dispersed, and this created an inherent right in children to the possessions of their ancestors; (b) that the advantages of the incentive to be found in family fortunes were outweighed by the mischiefs to society of perpetuities; (c) the value of the French system in breaking down the tendency of primogeniture to aggregate property in masses; (d) the economic value of having a section of society relieved from immediate pressure.

Heavy taxation of bequest through death duties has been advocated on lines which are intended: (a) to produce a maximum revenue without hurting the subject of assessment; (b) to correct the natural anomalies of the bequest system; (c) to redistribute wealth; (d) to socialize or nationalize wealth.

The most modern and most considered scheme for virtual abolition of continuous inheritance is the Rignano proposal for death duties of a special type, progressive in point of time by the number of successions. When a man dies, under this system a large tax would be laid upon all wealth acquired by him through inheritance, and only a small one upon wealth saved by him in his own lifetime. As a result a certain corpus of wealth passes to his heir, and to that heir it is all inherited wealth, so that on his death in turn it would be very heavily taxed. It is claimed that every one would have to work and save hard, for it would only be from such self made wealth that the children could benefit. There are several Rignano schemes, varying in severity, from a mere modification of existing death duties, to the maximum profit which passes any given block of property into the hands of the State in two generations. The Colwyn Committee on Taxation and the National Debt reported against the Rignano plan as a scheme of taxation.

Economic Consequences of Inheritance.—The precise effects of a system of inheritance have never yet been worked out, so far as influence upon production, total savings and total national wealth is concerned. It is not known, for example, whether the European system of compulsory family division, or the British system of primogeniture combined with free bequest, have like effects. It is generally considered that primogeniture has concentrated landed estates, whereas the *légitime* has unduly dispersed them but it is not known whether the total economic product of the one can be said to be greater than the other. The small experience of a complete absence of rights of inheritance during the short period when this obtained in Russia, is too confused with other influences for any lesson to be drawn as to relative total productivity of the economic organism with or without

the inheritance system. In so far as the right to found a family and to make free bequests respectively—two quite different economic motives—are influences in the accumulation of capital, the British system may be said to be an influence in favour of maximum production. On the other hand, in so far as a number of capable individuals in society are enabled to draw to themselves a substantial portion of the annual national production without making any contribution to it, and in so far as the sight of this has a depressing influence on the producers, then important influences are at work restricting total production. Obviously these are questions of degree, and if the numbers of the idle rich are very great and the sentiment of resentment is proportionately strong, then the economic restriction through the system will be great enough to be an important offset to the psychology of saving.

With the invention of modern finance and joint stock enterprise, large aggregations of wealth can be secured for production in a way that was formerly only possible with inherited aggregations. To this extent we are less dependent upon concentration of wealth through inheritance. Moreover, the importance of continuity of family management in private business is becoming rapidly less with the growth of a salaried managing class. It may be said, therefore, that the advantages of a system of inheritance from the point of view of national production rest almost entirely in its psychological influence upon saving, and not upon objective forms of production made possible only by the system.

Relation to Distribution of Wealth.—The more important economic considerations relate, however, to the *distribution* of wealth rather than to total wealth, especially as men are so constituted that they prefer to have a large share of an aggregate they do not realize is small, than a small share of an aggregate that would be much greater. In other words, it is the comparative share of wealth rather than the absolute amount that affects many people's economic contentment and their economic motives. It is often held that inherited wealth is the main determining factor in the extremely unfair distribution of wealth; but while it is undoubtedly contributory, the question as to the extent to which unevenly distributed wealth is an economic, as distinct from a moral, evil remains unsolved, and whether inheritance is really the predominant factor, is also undetermined. Some doubt is thrown upon the assumption that a very large portion of existing estates has not actually been amassed in the lifetime of the deceased, when one bears in mind that the total national wealth of one or two generations ago is only a small proportion of the present total. Moreover, real property, to which aggregation through primogeniture formerly applied to a marked extent, is a decreasing portion of the total national wealth. The actual average destination of a given fortune, *i.e.*, whether it tends to form part of a larger aggregate higher up the scale of distribution, or to split into small fragments amongst a number of holders lower down the scale, is by no means certain. There are indications, moreover, that the number of people holding large inherited fortunes, who are capable of contributing to the national income, is popularly over-estimated, when one eliminates children, old people and those who render important public services for no direct payment. The economic effects, in general, of inheritance are much less clearly known than is assumed in popular discussion. A Committee of the British Association for the Advancement of Science, Section "F," has recently been appointed to endeavour to obtain more exact knowledge upon the subject.

Stamp, *Social Significance of Death Duties* (1925); J. Stamp, *Economic Factors* (1929); *Report of Committee on Taxation and the National Debt* (1927). (J. S.)

INHERITANCE TAX, the name given, in the United States, to a tax or charge upon property as it passes to heirs or legatees from a deceased person; known in Great Britain as death duties. Such a tax was levied by the Federal government at the time of the American Civil War and again from the time of the World War on. All but a few of the States also levy inheritance taxes, the amount varying greatly according to the State, the amount of the estate, the relationship of receiver to the decedent,

etc. The amount allowed as exemption also varies greatly from State to State.

INHIBITION, an act of restraint or prohibition, an English legal term, particularly used in ecclesiastical law, for a writ from a superior to an inferior court, suspending proceedings in a case under appeal. It applies also to the suspension of jurisdiction of a bishop's court on the visitation of an archbishop, and for that of an archdeacon on the visitation of a bishop. It is more particularly applied to a form of ecclesiastical *censure*, suspending an offending clergyman from the performance of any service of the Church, or other spiritual duty, for the purpose of enforcing obedience to a monition or order of the bishop or judge.

INIA (*Inia geoffrensis*), the fresh-water dolphin of the Amazon basin, reaching 8 ft. in length and pink, or black and pink in colour. (See CETACEA.)

INISFAIL, a poetical name for Ireland. It is derived from *inis* "island" and *Lia-fáil*, the celebrated stone, identified in Irish legend with the stone on which the patriarch Jacob slept when he dreamed of the heavenly ladder. The Lia-fáil was supposed to have been brought to Ireland by the Dedannans and set up at Tara as the "inauguration stone" of the Irish kings; it was subsequently removed to Scone where it became the coronation stone of the Scottish kings, until it was taken by James VI. of Scotland to Westminster and placed under the coronation chair in the Abbey, where it has since remained. Inisfail was thus the island of the Fáil, the island whose monarchs were crowned at Tara on the sacred inauguration stone.

INITIALS, the first letters of names. In English law it has been held that it is sufficient if a person affixes to a document the usual form in which he signs his name, with the intent that it shall be treated as his signature. So, signature by initials is a good signature within the Statute of Frauds (*Phillimore v. Barry*, 1818, 1 Camp. 513), and also under the Wills Act 1837 (*In re Blewitt*, 1880, 5 P.D. 116). (See SIGNATURE; AUTOGRAPH.)

INITIATIVE. The initiative is the form of direct legislation which enables the voters popularly to frame or direct a legislative body to enact a certain law. It is the companion popular agency to the referendum, which is the reference to the voters of an act of the legislature for approval or disapproval. The referendum may be either compulsory or optional, the difference being that if the former, it is inoperative until approved by the voters.

In the United States the first initiative and referendum law was passed by South Dakota in 1898. Utah followed in 1900, Oregon in 1902, Nevada in 1904, Montana in 1906, Oklahoma in 1907, Maine, Missouri and Michigan in 1908, Arkansas and Colorado in 1910, California and Arizona in 1911, Idaho, Ohio, Nebraska and Washington in 1912, Mississippi and North Dakota in 1914 and Massachusetts in 1918. New Mexico passed a referendum law in 1911 and Maryland in 1915. The New Mexico and Utah laws have never been used because of difficult requirements for the petitions. The Mississippi law was declared unconstitutional. Many cities in other States under the commission and managerial forms of government have adopted the initiative and referendum.

Petitions must be circulated and signed by a requisite number of voters before a matter may be initiated before the legislature, or an act already passed may be submitted in referendum to the voters. The legislature may, by its own volition, submit an act to a referendum.

The Federal constitutionality of the initiative and referendum were tested in 1906, when the Oregon law was attacked as in violation of the guarantee to each State of a republican form of government as provided by s. 4 of Article IV. of the Constitution. The Supreme Court held in *Pacific States Telephone Co., etc., v. Oregon*, 223 U.S. 118, that it was a political rather than a judicial case, thus dismissing it.

The initiative and referendum are used principally in acts and proposed acts involving the direct primary, State prohibition enforcement, regulation of public utilities, education and taxation. Oregon, Montana, Oklahoma, California, Arizona, Colorado, Nebraska, Ohio, Washington, Utah, North Dakota and Massachu-

setts have passed laws providing for the distribution of pamphlets to the voters concerning the questions to be voted upon. The Colorado act remains inoperative because of the failure to repeal a conflicting provision in the State Constitution.

INJECTOR, an induced current apparatus which by means of a jet of steam feeds water to a boiler. The invention of Henri Giffard, its introduction in 1859 created great interest, because it seemed impossible that a jet of steam from a boiler could force itself and the water back into the boiler. Yet not only this was done, but later researches proved that exhaust steam at atmospheric pressure could be utilized, and it is possible now to deliver against a pressure of 150 lb. per sq. in. The Davies and Metcalfe exhaust injector will do this, and with the help of a small supplementary jet of live steam it will feed against a pressure of 250 lb. per sq. in. Exhaust steam has no velocity in the atmosphere, but if issued into a vacuum it acquires a very high velocity; hence by condensing the steam by contact with the feed water such a vacuum is produced, the velocity of the steam, imparted to the water, giving sufficient force to carry the latter into the boiler. (See also EJECTOR; STEAM, GENERATION OF.)

INJUNCTION, in English law, the name for a judicial command whereby a party is required to refrain from doing a particular thing according to the exigency of the writ. Formerly it was a remedy peculiar to the court of chancery, but under the present constitution of the judicature, the injunction is now equally available in all the divisions of the high court of justice, and it can no longer be used to prevent an action in any of them from proceeding in the ordinary course.

Although an injunction is properly a restraining order, there are instances in which, under the form of a prohibition, a positive order to do something is virtually expressed by what is known as a "mandatory" injunction. The injunction was used to stay proceedings in other courts "wherever a party by fraud, accident, mistake or otherwise had obtained an advantage in proceeding in a court of ordinary jurisdiction, which must necessarily make that court an instrument of injustice." As the injunction operates personally on the defendant, it may be used to prevent applications to foreign judicatures; but it is not used to prevent applications to parliament, or to the legislature of any foreign country, unless such applications be in breach of some agreement, and relate to matters of private interest. The jurisdiction of the court to prevent breaches of contract has been described as supplemental to its power of compelling specific performance; thus, e.g., in the case of an agreement of a singer to perform at the plaintiff's theatre and at no other, the court, although it could not compel her to sing, could by injunction prevent her from singing elsewhere in breach of her agreement.

An injunction may as a general rule be obtained to prevent acts which are violations of legal rights, except when the same may be adequately remedied by an action for damages at law. Thus the court will interfere by injunction to prevent waste, or the destruction by a limited owner, such as a tenant for life, of things forming part of the inheritance. Injunctions may also be obtained to prevent the continuance of nuisances, public or private, the infringement of patents, copyrights and trade marks. Trespass might also in certain cases be prevented by injunction. Purely temporary injunctions may be obtained *ex parte* but others only on notice to the other side.

An injunction obtained on interlocutory application during the progress of an action is called an "interim" injunction, which is superseded by the trial. It may be continued either provisionally or permanently. (See MANDAMUS.)

For the analogous practice in Scots law see INTERDICT. (X.)

United States.—Despite the administration of law and equity by a single court, as is true of most American States, the remedy by injunction retains its essentially equitable character. Its issuance is governed, in the main, by the accepted precedents of equity. A recent extension of the injunction on the principle of

equitable jurisdiction over nuisances is the use of the remedy to aid in the enforcement of criminal laws. The fact that the proceedings relating to the issuance and enforcement of injunctions are conducted before a judge alone, eliminates the inevitable discretion that under the common law system is vested in a jury. Consequently, when the enforcement of a particular law becomes difficult because of the opposition of a particular community as manifested in the tendency of juries to acquit in criminal prosecutions, resort has been made to this head of equity jurisdiction. The popularly termed "padlock injunction" established by the National Prohibition Act, which results in prohibiting for a period of time any use of the premises in which liquor has been sold, is the most marked example of this type. Its effectiveness is attested to by the adoption of similar remedies by the numerous State prohibition acts.

Peculiar to the American federalist system is the problem of Federal courts enjoining proceedings in State courts and vice versa. The general principle is that no such injunctions shall issue; but being courts of concurrent jurisdiction either court that first obtains jurisdiction of the subject matters regards itself as entitled to retain that jurisdiction to the exclusion of the other court and employs the injunction in aid of this purpose. The friction that might result from a liberal use of the injunction was foreseen at an early date, and in 1793 Congress prohibited the use of the injunction by the Federal courts for this purpose save in bankruptcy cases. The Federal courts have, however, by a series of judicial decisions established numerous exceptions to this broad statutory provision among which is that noted above and the principle that the injunction will issue in aid of the exclusive jurisdiction of the Federal courts. A second ground of irritation concerned the use of the injunction by the Federal courts to restrain the enforcement of State statutes on the ground of their constitutionality. An appeal from such action lay to the U.S. Supreme Court, but during the interim a single Federal judge was able to set at naught the entire administrative authority of a State. The incongruity of this result led Congress by a series of statutes beginning in 1910 to prohibit the issuance of such injunctions before a court consisting of less than three judges, one of whom should be a circuit judge, and to provide for expediting an appeal therefrom to the Supreme Court. Limitations have also been imposed upon the power of Federal judges to issue *ex parte* restraining orders pending an application for a temporary injunction. (J. M. LA.)

Injunctions in Labour Disputes.—The devices to induce the employer to yield to demands of organized labour through economic and social pressure are, broadly, the strike, the picket line, the boycott. The application of these instruments is illegal in all jurisdictions when accompanied by violence, intimidation or physical coercion; but is permissible in many States when free from those vices if the end sought to be achieved thereby be deemed a justification for the immediate damage inflicted upon the complainant. The Anglo-Saxon legal system provides three remedies for acts that cause damage unjustifiably: an action at law for damages, criminal proceedings if the infliction of damage amounts to a crime, and the equitable action for an injunction to restrain the commencement or continuance of damaging acts threatened or begun. The English case of *Springhead Spinning Co. v. Riley* (1868) L.R. 6 Eq. 551, in approving injunctive relief against the publishing of placards of an intimidating nature in the course of a labour dispute, supplied the precedent for the earliest American cases in the decade following 1884. The *Debs* case in 1895 (158 U.S. 564), which granted an injunction at the suit of the national Government, gave final sanction to the propriety of equitable relief in labour controversies. Within the next decade instances of labour injunctions multiplied so extensively as to evoke, in the words of a Supreme Court justice, a "controversy over the remedy (that) overshadowed in bitterness the question of the relative substantive rights of the parties" (*Truax v. Corrigan*, 257 U.S. 312, 366). In the period prior to the enactment of corrective legislation in 1914, there issued from American courts well over 500 injunctions; and after 1914, despite the Federal legislation, duplicated in many States, the number of injunctions con-

tinued unabated.

Practice.—The propriety of equitable relief in labour controversies has been sustained upon the grounds of actual or imminent injury to the complainant's property rights, inadequacy of the remedy at law, the financial irresponsibility of the individual defendants and the desirability of avoiding a multiplicity of actions at law.

Injunctions are of three general classes: (1) the temporary restraining order or injunction *ad interim*, which issues upon the filing of the bill of complaint, without notice to the opposing side or opportunity to be heard, on the ground that irreparable damage might be inflicted before a hearing could be had; (2) the temporary injunction or injunction *pendente lite*, which issues after notice and opportunity of the defence to be heard upon its countervailing affidavits. This hearing is only full enough to enable the judge to decide upon the probabilities of the situation. The court's discretion is "of the broadest and is seldom interfered with"; (3) the permanent injunction which issues after extended hearings and final decision on the merits.

The case is given a formal hearing before a judge and without a jury; facts are generally ascertained through sworn written statements or affidavits rather than through testimony in open court tested by cross-examination. A violation of the injunction, at any of its stages, whether or not the act is independently a crime, is a contempt of court. The alleged contemnor is tried before the judge who granted the injunction and (in the absence of contrary legislation) without a jury; the normal mode of proof is by affidavit, though some courts in recent years have summoned witnesses to establish the facts; the punishment of those adjudged guilty is in the discretion of the court and in fact has ranged from a small fine to imprisonment for days and months.

The injunction issues against the parties defendant who have been subjected to the court's jurisdiction. Frequently, especially in the Federal courts, an *omnibus* clause is added in order to extend the prohibitions of the decree to "all persons combining and conspiring with the defendants and all other persons whomsoever" (e.g., *In re Debs*, 158 U.S. 564); then the persons served with the decree and "all persons generally" who have actual knowledge thereof are bound to its obedience at the peril of being cited for contempt of court (*Ex parte Lennon*, 166 U.S. 546). The restraining clauses of the injunction, intended to embrace whatever conduct the court deems illegal, have become more and more elaborate, owing in large degree to the fact that the decree is customarily approved as prepared by counsel for the complainant. The proscriptions have included not only acts of violence, intimidation and threats, but also the display of "unfair" banners and placards, "unlawful persuasion" of employees to quit work or of customers to withhold patronage, the payment of strike benefits and, at times, the calling of a strike or its conduct by trade union officers. They have included restrictions upon speech—"abusive language," "bad language," "opprobrious epithets," "jeers, entreaties, argument, persuasion, taunts." They have incorporated *omnibus* interdictions by restraining damage "in any way," "in any way whatsoever," "in any manner directly or indirectly." (See text of restraining clauses of two Federal injunctions in 37 *Harvard Law Rev.* 1101.)

More recently, however, appellate courts have modified decrees whose phrasing barred lawful acts with the unlawful; they have even given affirmative suggestions as to what acts remained permissible and have defined them in detail.

Criticism.—Criticism, with more or less virulence, has been continuous since the *Debs* case. It has been said that equity replaces the enforcing agencies of the criminal law by a summary procedure lacking the traditional safeguards for the accused. Observation has been made that injunctions have abridged the constitutional guaranties of free speech, free press and peaceful assembly; that they are of broad scope and vague terminology, encircling the obviously lawful activities with undefined fringes that make of the whole merely "sweeping injunctions to obey the law"; that, as a result, the persons affected are paralyzed even in the exercise of conceded rights, for they are left guideless in the determination of what conduct remains permitted them in the

carrying on of the struggle, any effective activity inviting prosecution for contempt. In later years, much of the resentment has centred upon the temporary restraining order which is granted without substantial proof, and upon the temporary injunction. The crucial issues are preponderantly controversies of fact. But courts often resolve them from diametrically contradictory affidavits, by granting the decree on the theory that only illegal conduct is restrained thereby and that possible errors will be corrected upon the final hearing. It has been pointed out that the temporary injunction is for all practical purposes the final stage in the litigation; owing to the termination of the strike meanwhile, lack of funds, or a consciousness of futility, the defendants infrequently carry on the contest. On the other hand, the injunction in labour disputes has been defended as the most efficient device to stay the illegal damage to persons and property frequently incidental to a strike.

Legislation.—The serious criticism of the propriety of the injunctions in labour disputes provoked State legislatures and Congress to efforts at corrective measures. Arizona in 1913 enacted legislation forbidding the issue of injunctions in labour disputes "unless necessary to prevent irreparable injury to property" and denying the power of courts of equity to restrain "any person or persons from terminating any relation of employment or from ceasing to perform any work or labour or from recommending, advising, or persuading others by peaceful means so to do; or from attending at or near a house or place where any person resides or works, or carries on business, or happens to be for the purpose of peacefully obtaining or communicating information, or of peacefully persuading any person to work or to abstain from working; or from ceasing to patronize or to employ any party to such dispute; or from recommending, advising, or persuading others by peaceful means so to do. . . ." The Supreme Court of the United States (four justices dissenting) held the statute to entail a deprivation of property without due process of law, a denial of the equal protection of the laws and, therefore, a contravention of the 14th amendment to the Constitution of the United States (*Truax v. Corrigan*, 1921, 257 U.S. 312).

The Clayton Act passed by Congress in 1914 used language (s. 20) essentially similar to that of the Arizona statute but was construed by the U.S. Supreme Court as "merely declaratory of what had always been the law and the best practice in equity"; the injunction might still issue against picketing deemed unlawful by the court (*American Steel Foundries v. Tri-City Trade Council*, 1921, 257 U.S. 184) and against the secondary boycott (*Bedford Cut Stone Co. v. Journeymen Stonecutters' Assoc.*, 1927, 274 U.S. 37). Subsequent State legislation, following s. 20 of the Clayton Act, received a corresponding construction (*Gexas v. Greek Restaurant Workers' Club, et al.*, 1926, 99 N.J. Eq. 770).

Section 22 of the Clayton Act granted the right of jury trial in proceedings for indirect contempt, where the act alleged to constitute the contempt is also a crime. This provision survived an attack based upon the doctrine that the power of a court of equity could not be restricted because inherent and derived from the constitutional grant of judicial power (*Michaelson v. United States*, 1924, 266 U.S. 42). In Massachusetts, the doctrine of separation of powers prevailed (*Walton Lunch Co. v. Kearney*, 1920, 236 Mass. 310). Section 17 of the Clayton Act restricted the issue of temporary restraining orders without notice and required a hearing to be held within ten days after issue of such order; s. 19 required the injunction to be specific in terms. In the 70th Congress (Dec., 1927), new legislation was introduced, further restricting the use of injunctions in labour disputes in the Federal courts.

BIBLIOGRAPHY.—The decisions of most importance and interest in the U.S. Supreme Court and in the lower Federal courts in addition to those mentioned above are: *Gompers v. Bucks Stove and Range Co.* (1911) 221 U.S. 418; *Hitchman Coal and Coke Co. v. Mitchell* (1917) 245 U.S. 229; *Duplex Printing Press Co. v. Deering, et al.* (1920) 254 U.S. 443; *U.S. v. Ry. Employees' Dept. of American Fed. of Labor, et al.* (D.C. N.D. Ill. 1922) 283 Fed. 479, 286 Fed. 228, 290 Fed. 978; *Great Northern Ry. Co. v. Brosseau* (D.C.N. Dak. 1923) 286 Fed. 414.

Decisions in State Courts are *Bossert v. Dhuy* (1917) 221 N.Y. 342; *Auburn Draying Co. v. Wardell* (1919) 227 N.Y. 1; *Exchange Bakery and Restaurant, Inc. v. Rifkin, et al.* (1927) 245 N.Y. 260; *Interbor-*

ough Rapid Transit Co. v. Lavin (1928) 247 N.Y. 65; *Vegetahn v. Gunner* (1896), 167 Mass. 92; *Pierce v. Stablemen's Union* (1909), 156 Cal. 70; *Greenfield v. Central Labor Council* (1922), 104 Oregon 236; *Keuffel and Esser v. Int. Assoc. Machinists* (1922), 93 N.J. Eq. 429; *Jefferson and Indiana Coal Co. v. Marks, et al.* (1926), 287 Pa. 171.

The most important collection of source authorities is Sayre, *Cases on Labor Law* (1922). The leading legal discussions of the subject are:—W. H. Dunbar, "Government by Injunction" (1897), 13 *Law Quarterly Review* 347; E. E. Witte, "Value of Injunctions in Labor Disputes" (1924), 32 *Journal of Pol. Econ.*, and "Results of Injunctions in Labor Disputes" (1922), 12 *Amer. Labor Legist. Rev.*; G. W. Pepper, "Injunctions in Labor Disputes" (1924), 49 *Rep. of the Amer. Bar Assn.*, 174; Frankfurter and Greene, "The Use of the Injunction in American Labor Controversies" (1928), 44 *Law Quart. Review* 164, 353; T. R. Powell, "The Supreme Court's Control over the Issue of Injunctions in Labor Disputes," 13 *Proceedings of the Academy of Political Science* (June, 1928); Mason, *Organized Labor and The Law* (1925); Commons and Andrews, *Principals of Labor Legislation* (1920); Annotations in 34 *Harv. L. Rev.* 884, 40 *Harv. L. Rev.* 886, 41 *Harv. L. Rev.* 908.

Testimony taken in the course of Congressional hearings is valuable. The references to 1914 are collected by Mr. Justice Brandeis in his dissenting opinion to *Truax v. Corrigan* (1921), 257 U.S. 312, 354, 369-370. Add Senate hearings on S. 1482, 70th Cong. 1st Sess. (Feb.-March 1928), limiting scope of injunctions in labor disputes. (N. G.)

INK, in its widest signification, a substance employed for producing graphic tracings, inscriptions, or impressions on paper or similar materials. The term includes two distinct conditions of pigment or colouring matter; the one fluid, and prepared for use with a pen or brush, as writing ink; the other a glutinous adhesive mass, printing ink, used for transferring to paper impressions from types, engraved plates and similar surfaces.

Writing Inks.—Writing inks are fluid substances which contain colouring matter either in solution or in suspension, and commonly partly in both conditions. They may be prepared in all shades of colour, and contain almost every pigment which can be dissolved or suspended in a suitable medium. The most important of all varieties is black ink, after which red and blue are most commonly employed. Apart from colour there are special qualities which recommend certain inks for limited applications, such as marking inks, ineradicable ink, sympathetic ink, etc. A good writing ink for ordinary purposes should continue limpid, and flow freely and uniformly from the pen; it should not throw down a thick, sludgy deposit on exposure to the air; nor should a coating of mould form on its surface. It should yield distinctly legible characters immediately on writing, not fading with age; and the fluid ought to penetrate into the paper without spreading, so that the characters will neither wash out nor be readily removed by erasure. Further, it is desirable that ink should be non-poisonous, that it should as little as possible corrode steel pens, that characters traced in it should dry readily on the application of blotting paper without smearing, and that the writing should not present a glossy, varnished appearance.

Tannin inks are prepared from galls, or other sources of tannin, and a salt of iron, with the addition of some agglutinant in the case of the so-called oxidized inks, or a colouring matter in the case of unoxidized inks. Such mixtures form the staple black inks of commerce; they are essentially an insoluble iron gallate in extremely fine division held in suspension in water or a soluble compound dissolved in water. On long exposure to air, as in ink-stands or otherwise, tannin inks gradually become thick and ropy, depositing a slimy sediment.

Ordinary Black Ink.—The essential ingredients of ordinary black ink are—first, tannin-yielding bodies, for which Aleppo or Chinese galls are the most eligible materials; second, a salt of iron, ferrous sulphate (green vitriol) being alone employed; and third, a gummy or mucilaginous agent to keep in suspension the insoluble tinctorial matter of the ink. For ink-making the tannin has first to be transformed into gallic acid. In the case of Aleppo galls this change takes place by fermentation when the solution of the galls is exposed to the air, the tannin splitting up into gallic acid and sugar. Chinese galls do not contain the ferment necessary for inducing this change; and to induce the process yeast must be added to their solution. To prepare a solution of Aleppo galls for ink-making, the galls are coarsely powdered, and intimately mixed with chopped straw. This mixture is thrown into a

narrow, deep oak vat, provided with a perforated false bottom, and having a tap at the bottom for drawing off liquid. Over the mixture is poured lukewarm water, which, percolating down, extracts and carries with it the tannin of the galls. The solution is drawn off and repeatedly run through the mixture to extract the whole of the tannin, the water used being in such proportion to the galls as will produce as nearly as possible a solution having 5% of tannin. The object of using straw in the extraction process is to maintain the porosity of the mixture, as powdered galls treated alone become so slimy with mucilaginous extract that liquid fails to percolate the mass. For each litre of the 5% solution about 45 grams of the iron salt are used, or about 100 parts of tannin for 90 parts of crystallized green vitriol.

These ingredients when first mixed form a clear solution, but on their exposure to the air oxidation occurs, and an insoluble blue-black ferrosulfuric gallate in extremely fine division, suspended in a coloured solution of ferrous gallate, is formed. To keep the insoluble portion suspended, a mucilaginous agent is employed, and those most available are gum senegal and gum arabic. An ink so prepared develops its intensity of colour only after some exposure; and after it has partly sunk into the paper it becomes oxidized there, and so mordanted into the fibre. As the first faintness of the characters is a disadvantage, it is a common practice to add some adventitious colouring matter to give immediate distinctness, and for that purpose either extract of logwood or a solution of indigo is used. When logwood extract is employed, a smaller proportion of extract of galls is required, logwood itself containing a large percentage of tannin. For making an unoxidized or blue-black ink indigo is dissolved in strong sulphuric acid, and the ferrous sulphate, instead of being used direct, is prepared by placing in this indigo solution a proper quantity of scrap iron. To free the solution from excess of uncombined acid, chalk or powdered limestone is added, whereby the free acid is fixed and a deposit of sulphate of lime formed. A solution so prepared, mixed with a tannin solution, yields a very limpid sea-green writing fluid, and as all the constituents remain in solution no gum or other suspending medium is necessary. In consequence the ink flows freely, is easily dried and is free from the glossy appearance which arises through the use of gum.

Chinese Ink.—China ink or Indian ink is the form in which ink was earliest prepared, and in which it is still used in China and Japan for writing with small brushes instead of pens. It is extensively used by architects, engineers and artists generally, and for various special uses. China ink is prepared in the form of sticks and cakes, which are rubbed down in water for use. It consists essentially of lamp-black in very fine condition, baked up with a glutinous substance; and the finer oriental kinds are delicately perfumed.

Logwood Ink.—Under the name of chrome ink a black ink was discovered by Runge, which held out the promise of cheapness combined with many excellent qualities. It is prepared by dissolving 15 parts of extract of logwood in 900 parts of water, to which four parts of crystallized sodium carbonate are added. A further solution of one part of potassium chromate (not bichromate) in 100 parts of water is prepared, and is added very gradually to the other solution with constant agitation. The ink so obtained possesses an intense blue-black colour, flows freely and dries readily, is neutral in reaction and hence does not corrode steel pens, and adheres to and sinks into paper so that manuscripts written with it may be freely washed with a sponge without danger of smearing or spreading. It forms a good copying ink, and it possesses all the qualities essential to the best ink; but on exposure to air it very readily undergoes decomposition, the colouring matter separating in broad flakes, which swim in a clear menstruum. It is affirmed by Viedt that this drawback may be overcome by the use of soda, a method first suggested by Böttger.

Logwood forms the principal ingredient in various other black inks used especially as copying ink. A very strong decoction of logwood or a strong solution of the extract with ammonium-alum yields a violet ink which darkens slowly on exposure. Such an ink is costly, on account of the concentrated condition in which the logwood must be used. If, however, a metallic salt is introduced,

a serviceable ink is obtained with the expenditure of much less logwood. Either sulphate of copper or sulphate of iron may be used, but the former, which produces a pleasing blue-black colour, is to be preferred.

Aniline Inks.—Solutions of aniline dyestuffs in water are widely used as inks, especially coloured varieties. They are usually fugitive. Nigrosine is a black ink, which, although not producing a black so intense as common ink, possesses various advantages. Being perfectly neutral, it does not attack pens; it can easily be kept of a proper consistency by making up with water; and its colour is not injuriously affected by the action of acids. Its ready flow from stylographic pens led to the name "stylographic ink." Other aniline inks are mentioned below.

Ink which yields by means of pressure an impression, on a sheet of damped tissue paper, of characters written in it is called copying ink. Any ink soluble in water, or which retains a certain degree of solubility, may be used as copying ink. Runge's chrome ink, being a soluble compound, is, therefore, so available; and the other logwood inks as well as the ordinary ferrous gallate inks contain also soluble constituents, and are essentially soluble till they are oxidized in and on the paper after exposure to the air. To render these available as copying inks it is necessary to add to them a substance which will retard the oxidizing effect of the air for some time. For this purpose the bodies most serviceable are gum arabic or senegal, with glycerin, dextrin or sugar, which last, however, renders the ink sticky. These substances act by forming a kind of glaze or varnish over the surface of the ink which excludes the air. At the same time when the damp sheet of tissue paper is applied to the writing, they dissolve and allow a portion of the yet soluble ink to be absorbed by the moistened tissue. As copying ink has to yield two or more impressions, it is necessary that it should be made stronger, *i.e.*, that it should contain more pigment or body than common ink. It, therefore, is prepared with from 30 to 40% less of water than non-copying kinds; but otherwise, except in the presence of the ingredients above mentioned, the inks are the same. Copying ink pencils consist of a base of graphite and kaolin impregnated with a very strong solution of an aniline colour, pressed into sticks and dried.

Red and Blue Inks.—The pigment most commonly employed as the basis of red ink is Brazil-wood. Such an ink is prepared by adding to a strong decoction of the wood a proportion of stannous chloride (tin spirits), and thickening the resulting fluid with gum arabic. In some instances alum and cream of tartar are used instead of the stannous chloride. Cochineal is also employed as the tinctorial basis of red ink; but, while the resulting fluid is much more brilliant than that obtained from Brazil-wood, it is not so permanent. A very brilliant red ink may be prepared by dissolving carmine in a solution of ammonia, but this preparation must be kept in closely stoppered bottles. A useful red ink may also be made by dissolving the rosein of Brook, Simpson and Spiller in water, in the proportion of one to from 150 to 200 parts.

For the production of blue ink the pigment principally used is Prussian blue. It is first digested for two or three days with either strong hydrochloric acid, sulphuric acid or nitric acid, the digested mass is next very largely diluted with water, and after settling the supernatant liquid is siphoned away from the sediment. This sediment is repeatedly washed, till all traces of iron and free acid disappear from the water used, after which it is dried and mixed with oxalic acid in the proportion of eight parts of Prussian blue to one of the acid, and in this condition the material is ready for dissolving in water to the degree of colour intensity necessary. An aniline blue ink may be prepared by dissolving one part of bleu de Paris in from 200 to 250 parts of water.

Marking Ink.—The ink so called, used principally for marking linen, is composed of a salt of silver, usually the nitrate, dissolved in water and ammonia, with a little provisional colouring matter and gum for thickening. The colour resulting from the silver salt is developed by heat and light; and the stain it makes, although exceedingly obstinate, gradually becomes a faint brownish-yellow. Many vegetable juices, *e.g.*, of *Coriaria thymifolia*, *Semecarpus anacardium*, *Anacardium occidentale* (Cashew), are inks of this type.

Gold and silver inks are writing fluids in which gold and silver, or imitations of these metals, are suspended in a state of fine division. In place of gold, Dutch leaf or mosaic gold is frequently substituted, and bronze powders are used for preparing a similar kind of ink. The metallic foil is first carefully triturated into a fine paste with honey, after which it is boiled in water containing a little alkali, and then repeatedly washed in hot water and dried at a gentle heat. A solution is prepared consisting of one part of pure gum arabic and one part of soluble potash glass in four parts of distilled water, into which the requisite quantity of the metallic powder prepared is introduced. Owing to the superior covering nature of pure gold, less of the metal is required than is necessary in the case of silver and other foils. In general one part of foil to three or four parts of solution is sufficient. The metallic lustre of writing done with this solution may be greatly heightened by gently polishing with a burnishing point. Another gold ink depends upon the formation of purple of Cassius; the linen is mordanted with stannous chloride, and the gold applied as a gummy solution of the chloride.

Indelible or incorrodible ink is the name given to various combinations of lamp-black or other carbonaceous material with resinous substances used for writing which is exposed to the weather or to the action of strong acids or alkaline solutions. An ink having great resisting powers may be conveniently prepared by rubbing down Indian ink in common ink till the mixture flows easily from the pen. Other combinations have more the character of coloured varnishes.

Sympathetic inks are preparations used for forming characters which only become visible on the application of heat or of some chemical reagent. Many chemicals which form in themselves colourless solutions, but which develop colour under the influence of reagents, may be used as sympathetic ink, but they are of little practical utility. Characters written in a weak solution of galls develop a dark colour on being treated with a solution of copperas; or, vice versa, the writing may be done in copperas and developed by the galls solution. Writing done in various preparations develops colour on heating which fades as the paper cools. Among such substances are solutions of the chlorides of cobalt and of nickel. Very dilute solutions of the mineral acids and of common salt and a solution of equal parts of sulphate of copper and sal-ammoniac act similarly. Writing with rice water and developing with iodine was a device much used during the Indian Mutiny.

Printing Inks.—Printing inks are essentially mixtures of a pigment and a varnish. The varnish is prepared from linseed oil, rosin and soap; the oil must be as old as possible; the rosin may be black or amber; and the soap, which is indispensable since it causes the ink to adhere uniformly to the type and also to leave the type clean after taking an impression, is yellow, or turpentine soap for dark inks, and curd soap for light inks. The varnish is prepared as follows: The oil is carefully heated until it "strings" properly, *i.e.*, a drop removed from the vessel on a rod, when placed upon a plate and the rod drawn away, forms a thread about $\frac{1}{2}$ in. long. The rosin is carefully and slowly added and the mixture well stirred. The soap is then stirred in. The ink is prepared by mixing the varnish with the pigment, and grinding the mass to impalpable fineness either in a levigating mill or by a stone and muller. For black ink, lamp-black mixed with a little indigo or Prussian blue is the pigment employed; for wood engravings it may be mixed with ivory black, and for copper plates with ivory or Frankfurt black; for lithographic reproductions Paris black is used. Red inks are made with carmine or cochineal; red lead is used in cheap inks, but it rapidly blackens. Blue inks are made with indigo or Prussian blue; yellow with lead chromate or yellow ochre; green is made by mixing yellow and blue; and purple by mixing red and blue.

INKBERRY (*Ilex glabra*), a North American shrub of the holly genus (family Aquifoliaceae), known also as evergreen winter-berry and Appalachian tea, native to sandy soil from Nova Scotia to Florida and west to Louisiana, mostly near the coast. It is a small shrub, 2 ft. to 6 ft. high, with leathery, evergreen, oblong, usually slightly toothed leaves; small white flowers, solitary or sometimes two or three together, borne on short slender

stalks in the axils of the leaves, and black berry-like (drupe), about $\frac{1}{2}$ in. in diameter, ripening in autumn. Among other plants called ink-berry are the West Indian indigo-berry (*Randia aculeata*) and the widely distributed poke-berry (*Phytolacca decandra*). The Australian or Queensland ink-berry is *Mollinedia macrophylla*, a plant of the family Monimiaceae. (See HOLLY; POKE-BERRY.)

INKERMAN, BATTLE OF, fought on Nov. 5, 1854, between a portion of the allied British and French army besieging Sevastopol and a Russian army under Prince Menshikov (see CRIMEAN WAR). This battle derives its name from a ruin on the northern bank of the river Tchernaya near its mouth, but it was fought some distance away, on a nameless ridge (styled Mt. Inkerman after the event) between the Tchernaya and the Careenage Ravine, which latter marked the right of the siege-works directed against Sevastopol itself. Part of this ridge was occupied by the British, while farther to the south a French corps under General Bosquet was posted to cover the rear of the besiegers. The Russians arranged for a combined attack on the ridge by part of Menshikov's army (16,000) and a corps (19,000) that was to issue from Sevastopol. This attack was to have, beside its own field artillery, the support of 54 heavy guns, and the Russian left wing on the Balaklava battleground was to keep Bosquet occupied. If successful, the attack on the ridge was to be the signal for a general attack all along the line. It was apparently intended by Menshikov that the column from the field army should attack the position from the north, and that the Sevastopol column should advance along the west side of the Careenage Ravine. But he only appointed a commander to take charge of both columns at the last moment, and the want of a clear understanding as to what was to be done militated against success from the first. Soimonov, with the Sevastopol column, assembling his troops before dawn, led them on to the upland east of Careenage Ravine, while the field army column, under Pavlov, crossed the Tchernaya near its mouth, almost at right angles to Soimonov's line of advance.

The British troops on or near the ground were the 2nd Division, 3,000, encamped on the ridge; Codrington's brigade of the Light Division, 1,400, on the slopes west of the Careenage Ravine; and the Guards Brigade, 1,350, about $\frac{1}{2}$ m. in rear of the 2nd Division camp. No other forces, French or British, were within 2 m. except another part of Sir George Brown's Light Division. A mist overhung the field and the hillsides were slippery with mud. Soimonov, with his whole force deployed in a normal attack formation (three lines of battalion columns covered by a few hundred skirmishers) pushed forward along the ridge (6 A.M.) without waiting for Pavlov or for Dannenberg, the officer appointed to command the whole force.

Shell Hill, guarded only by a picquet, was seized at once. The heavy guns that had been brought from the fortress were placed in position on this hill, and opened fire (7 A.M.) on the knoll, 1,400 yds. to the south, behind which the 2nd Division was encamped. The Russian infantry halted for the guns to prepare the way, and the heavy projectiles both swept the crest of the British knoll and destroyed the camp in rear.

But already General Pennefather, commanding the division, had pushed forward one body of his infantry after another down the forward slope, near the foot of which they encountered the Russians in great force. On his side, Soimonov had been compelled to break up his regular lines of columns at the narrowest part of the ridge and to push his battalions forward a few at a time. This and the broken character of the ground made the battle even in the beginning a *mêlée*. The mist, which had at first allowed the big battalions to approach unobserved, now favoured the weaker side. Soimonov himself, however, formed up some

9,000 men, who drove back the British left wing—for the whole of Pennefather's force at the time was no more than 3,600 men. But the right wing, not as yet attacked, either by Soimonov or by Pavlov, held on to its positions on the forward slope, and a column of Russian sailors and marines, who had been placed under Soimonov's command and had moved up the Careenage Ravine to turn the British left, were caught, just as they emerged on to the plateau in rear of Pennefather's line, between two bodies of British troops hurrying to the scene of action. On the front, too, the Russian attack came to a standstill and ebbed, for Soimonov's overcrowded battalions jostled one another and dissolved on the narrow and broken plateau. Soimonov himself was killed, and the disciplined confidence and steady volleys of the defenders dominated the chaotic *élan* of the Russians. Thus 3,300 defenders were able to repulse and even to "expunge from the battlefield" the whole of the Sevastopol column, except that portion of it which drifted away to its left and joined Pavlov. This stage of the battle had lasted about 40 minutes. But, brilliant as was this overtone, it is the second stage of the battle that gives it its epic interest.

The first attack made by Pavlov's advanced guard, aided by parts of Soimonov's corps, was relatively slight, but General Dannenberg now arrived on the field, and arranged for an assault on the British centre and right, to be delivered by 10,000 men (half his intact forces) chiefly by way of the Quarry Ravine, the attack to be prepared by the guns of Shell Hill. Pennefather had been reinforced by the Guards Brigade and a few smaller units. Not the least extraordinary feature of the battle that followed is the part played by a sangar of stones at the head of Quarry Ravine and a small battery, called the Sandbag Battery, made as a temporary emplacement for two heavy guns a few days before. The guns had done their work and been sent back whence they came. Nevertheless, these two insignificant works, as points to hold and lines to defend on an otherwise featureless battlefield, became the centres of gravity of the battle.

The sangar at first fell into the hands of the Russians, but they were soon ejected, and small British detachments reoccupied and held it, while the various Russian attacks flowed up and past it and ebbed back into the Quarry Ravine. Possession of the Sandbag Battery was far more fiercely contested. The right wing was defended by some 700 men of the 2nd Division, who were reinforced by 1,300 of the Guards. The line of defence adjacent to the battery looked downhill for about 300yd., giving a clear field of fire for the new Enfield rifle the British carried; but a sharp break in the slope beyond that range gave the assailants plenty of "dead ground" on which to form up. For a time, therefore, the battle was a series of attacks, delivered with great fierceness by the main body of Pavlov's corps, the repulse of each being followed by the disappearance of the assailants. But the arrival of part of the British 4th Division under Sir George Cathcart gave the impulse for a counter-attack. Most of the division indeed had to be used to patch up the weaker parts of the line, but Cathcart himself with about 400 men worked his way along the lower and steeper part of the eastern slope so as to take the assailants of the battery in flank.

He had not proceeded far, however, when a body of Russians moving higher up descended upon the small British corps and scattered it, Cathcart himself being killed. Other counter-strokes that his arrival had inspired were at the same time made from different parts of the defensive front, and had the effect of breaking up what was a solid line into a number of disconnected bands, each fighting for its life in the midst of the enemy. The crest of the position was laid open and parts of the Russian right wing seized it. But they were flung back to the lower slopes of the Quarry Ravine by the leading French regiment sent by Bosquet. This regiment was quickly followed by others. The last great assault was delivered with more precision, if with less fury than the others, and had Dannenberg chosen to employ the 9,000 bayonets of his reserve, who stood idle throughout the day, to support the 6,000 half-spent troops who made the attack, it would probably have been successful.

As it was, supported by the heavy guns on Shell Hill, the as-

sailants, though no longer more than slightly superior in numbers, carried not only the sangar, but part of the crest line of the allied position. But they were driven back into the Quarry Ravine, and, relieving the exhausted British, the French took up the defence along the edge of the ravine, which, though still not without severe fighting, they maintained till the close of the battle. Inkerman, however, was not a drawn battle. The allied field artillery, reinforced by two long 18-pr. guns of the British siege train and assisted by the bold advance of two French horse-artillery batteries which galloped down the forward slope and engaged the Russians at close range, gained the upper hand. Last of all, the dominant guns on Shell Hill thus silenced, the resolute advance of a handful of British infantry decided the day, and the Russians retreated. The final shots were fired about 1.30 P.M.

The total British force engaged was 8,500, of whom 2,357 were killed and wounded. The French lost 939 out of about 7,000 who came on to the field, though not all these were engaged. The Russians are said to have lost 11,000 out of about 42,000 present. The percentage (27.7) of loss sustained by the British is sufficient evidence of the intensity of the conflict, and provides a convincing answer to certain writers who have represented the battle as chiefly a French affair. On the other hand, the reproaches addressed by some British writers to General Bosquet for not promptly supporting the troops at Inkerman with his whole strength are equally unjustifiable, for apparently Sir George Brown and Sir George Cathcart both declined his first offers of support, and he had Prince Gorchakov with at least 20,000 Russians in his own immediate front. He would therefore have risked the failure of his own mission in order to take part in a battle where his intervention was not, so far as he could tell, of vital importance. When Lord Raglan definitely asked him for support, he gave it willingly and eagerly, sending his troops up at the double, and it must be remembered that several British divisions took no part in the action for the same reason that actuated Bosquet. But, in spite of the seemingly inevitable controversies attendant on an "allied" battle, it is now generally admitted that, as a "soldiers' battle," Inkerman is scarcely to be surpassed in modern history.

INLAND REVENUE, BOARD OF. The period following the English Revolution of 1688 is on many accounts notable in the history of British public finance. Taxation, in particular, under the pressure of war with France, was reorganized in extent and character. In 1689 the Excise Board was reconstituted. Stamp duties were imposed and a Board of Stamps formed in 1694. A new tax on the yearly value of property, first imposed in 1692, was continued from 1697 by annual acts. For this, the ancient machinery for a time sufficed under which commissioners for divisions of every country had raised "aids" voted by parliament. A Board of Taxes was appointed in 1718. In 1797 Great Britain and Ireland were covered by six boards, of excise, stamps and taxes severally. Three excise boards were united in 1823. Ten years later stamps and taxes passed under joint administration. Finally, in 1849, the first Board of Inland Revenue embraced excise, stamps and taxes. In 1909 the excise passed to the Board of Customs, the Board of Inland Revenue retaining its title.

The board is constituted by letters patent, and consists of a chairman, a deputy chairman and three commissioners who are secretaries of the department and commissioners *ex officio*. The office is at Somerset House, London.

Scope and Functions.—The following are the sources of inland revenue:—

1. *Stamp Duties.* On documents of various kinds, which are inadmissible in evidence unless duly stamped.

2. *The "Death Duties."* These are stamp duties on documents connected with the administration of estates by executors and next of kin, or the receipt of property by beneficiaries. They comprise the estate duty, which is a tax on the capital value of property passing upon death, together with the legacy and succession duties.

3. *Income Tax and Super Tax.* The former is a flat-rate tax upon annual income or profits, as such. The latter is a surtax at rates graduated by reference to total income of the individual where this exceeds a certain sum. The surtax on the more affluent,

and a system of personal allowances and reliefs which effectively reduce the burden on smaller incomes, form the means of adjusting the incidence upon individuals. Other taxes included in inland revenue are comparatively insignificant.

In relation to income tax and the super tax, or surtax, the functions of the department extend to Great Britain and Northern Ireland; otherwise, to Great Britain alone.

Organization and Methods.—Stamp duties on documents requiring assessment are ascertained in the branch of the controller of stamps, at Somerset House. In commercial practice, the proper duty is often clear, and in such cases the document is normally drawn on stamped material. The stamps are for the most part impressed by means of dies, but adhesive stamps may be employed in certain cases. The death duties are assessed in the estate duty office at Somerset House.

Income Tax Methods.—Income tax is assessed locally. The income tax when imposed in 1842 was a lineal successor of the annual property tax of 1697. Local assessment was an inherited feature of the tax, which was, and still is, assessed by honorary commissioners for divisions of each county, with a surveyor of taxes intervening to safeguard the Crown. Appeals against assessments are also determined by these commissioners, and their functions in this respect constitute the most valuable and responsible part of their duties. Modern conditions have rendered the ascertainment of taxable profits often highly intricate, and liability is wherever possible, agreed by the surveyor (now the inspector) of taxes, before assessment. The tax inspectorate, organized in district offices, forms a branch under the direction of the chief inspector of taxes at Somerset House.

The district inspectors are also concerned in the reduction by the local commissioners where necessary, of income tax assessments, in carrying out the allowances and reliefs due to individual taxpayers, and in repayments. Income tax upon profits, being charged upon the business by which the profits are earned, is deducted from interest and dividends before receipt by the taxpayer (*collection "at the source"*) who therefore in numerous cases requires repayment.

Certain income tax assessments and all super tax, or surtax, assessments are made by the special commissioners of income tax, a body appointed by the Treasury. The basis of liability for super tax is income tax liability already determined, and the inspector of taxes therefore does not intervene. The special commissioners also determine appeals against assessments, and exercise their most important functions in this judicial capacity. As a judicial body the special commissioners, like the local commissioners, are independent of the Board of Inland Revenue.

In addition to the system of income tax and super tax appeals, there exists appropriate machinery for determination of all cases of disputed liability to revenue duties. The procedure issues ultimately in reference, where and so far as necessary, to the law Courts. A legal branch is maintained under the solicitor of inland revenue.

Payment of duties other than income tax is made direct to the department. Income tax is largely gathered by collectors, appointed locally. The accountant-general at Somerset House receives and makes payments, keeps necessary accounts and controls repayments and all expenditure. A valuation office is employed to value lands, tenements and hereditaments upon which death duties are payable. The branch of the director of stamping at Somerset House is responsible for the mechanical work of producing revenue stamps, and constitutes a factory of moderate size. A central office at Edinburgh, under the comptroller of stamps and taxes, Scotland, performs duties corresponding to those of the executive and accounting branches in London.

A report made by the board is annually laid before parliament. All accounts are audited by the comptroller and auditor-general, who is independent both of the department and of the Treasury.

The total cost of inland revenue services represents some 1.7% of the gross receipts. (*See ESTATE DUTIES; INCOME TAX.*)

BIBLIOGRAPHY.—*Reports of the Commissioners of Inland Revenue* (1857 and annually); *Report and Minutes of Evidence of Royal Commission on Income Tax* (1920). (W. V. Br.)

INLAND REVENUE DUTIES. These duties are described under the headings ESTATE DUTIES; INCOME TAX; DEATH DUTIES; STAMP DUTIES; LAND TAXES, etc.; *see* also the relevant sections of the articles GREAT BRITAIN and UNITED STATES.

INLAND WATER TRANSPORT. Transport by navigable waterways in the last years before the World War reached very high figures indeed. In 1875, 10,400,000 tons were carried by water in Germany; in 1910, 64,750,000 tons. The bulk of the increase was on the large rivers and canals; the less important waterways showed no advance, and in some cases actually a falling-off. In the Netherlands and Belgium the ports of Rotterdam, Amsterdam and Antwerp benefited by the great development of Rhenish industry in Germany, the Rhine being admirably suited for carrying both ores and coal. In the riparian states of the Danube the movement of industrial products downstream and of cereals and oil upstream has produced a similar increase in waterborne traffic. *See* also UNITED STATES, *Inland Water Ways*.

This general development of traffic by navigable waterways everywhere led to the undertaking of important hydraulic work in the construction of new waterways and the improvement of existing ones. Steps were taken to regulate and canalize rivers; canals were cut to link up important rivers; existing canals were enlarged so as to be navigable by vessels of larger tonnage; and gradually a whole network of navigable waterways has spread over central and western Europe. The total length of the navigable waterways in France before the war was more than 11,000 kilometres. In Germany it exceeded 10,000. The capacity of the German waterways was on the whole greater than that of the French, since many of the canals in France were navigable only for vessels of 300 tons or less.

Effects of the War.—The World War interrupted the development of inland navigation, and its termination was followed by a transport crisis due mainly to the disorganization of the railways through the wear and tear of rolling stock and rails, and the destruction of considerable portions of tracks and railway installations. Normal currents of traffic had to be re-established, and demobilization raised a difficult transport problem. Even the full use of navigable waterways was insufficient to meet immediate requirements. The destruction of many waterways with their works (bridges, locks, etc.) and of many vessels used in inland navigation, helped to make matters more difficult. But repairs were fairly quickly effected and in 1920–21, indeed, when the railway crisis was still acute in consequence of a shortage of rolling stock, there was a surplus of inland navigation tonnage owing to the considerable increase in freights due to the rise in the cost of living. Governments avoided or took measures to prevent any great increase in railway rates until the existence of large deficits showed that it was necessary to adapt rates to the increased expenditure. Navigation, on the other hand, being entirely in the hands of private individuals, had to adapt itself immediately to the increased working expenses.

Furthermore, governments in some cases used the railways to establish new currents of transport, which had become desirable in consequence of altered frontiers, or to help national seaports to compete with foreign seaports. Sometimes, too, by instituting competitive rates on the railways, governments tried to obtain larger receipts which would enable them to meet the deficit of the railway budget. Another factor which unfavourably affected the financial results of inland navigation concerns was the absence of proper upkeep of the waterways during the years 1914–18. Rivers which require constant attention suffered to a large extent in this respect, and it proved impossible to employ the rivercraft to their full capacity.

But the main cause of the bad conditions of inland navigation after the war was that financial and economic crises, the instability of the exchanges, and general impoverishment did not allow the resumption of transport which had been expected. Nevertheless, general improvement gradually took place.

In France the total amount of goods carried on rivers and canals, which was 41,896,754 tons in 1913, was only 21,500,000 in 1920. In 1924 the figure had risen to 36,758,000 tons, traffic assuming large dimensions in the north of France, especially in

regard to the port of Strasbourg. The following figures for the port of Paris may be noted: in 1913, 4,786,649 tons were loaded and 11,709,824 tons unloaded; the figures for 1924 were respectively 2,769,166 tons and 10,221,228 tons.

The total traffic for the Rhine, which in 1913 was 54,562,574 tons, had fallen in 1918 to 25,608,609 tons and by 1923 as low as 16,608,609 tons. In that year—a quite abnormal one, certainly, owing to the Ruhr occupation—traffic through the port of Duisburg-Ruhrort, which in 1913 was about 26,000,000 tons, and which was still 14,000,000 tons in 1922, fell to 3,980,412 tons.

The situation is exactly the same as regards traffic across the German-Dutch frontier near Lobith. Over 37,000,000 tons in 1913, it fell in 1918 to scarcely 5,000,000 tons, but by 1924 had risen again to 23,000,000 and in 1925 to about 40,000,000 tons. In 1926 (year of British coal strike) the traffic amounted to 52,000,000 tons of which nearly 38,000,000 was downstream.

On the Danube, in 1911, the total movement of goods was 6,802,639 tons and, in 1924, 3,757,010 tons. The year 1925 showed a considerable increase in traffic.

The same effects are observable in Russia, although, in this case, it is necessary to take account of the great disturbance caused by the collapse of the Tsarist régime in 1917 and the ensuing civil war, and the famine which ravaged the Volga basin in 1921. In 1913 the total weight of goods carried by water amounted to 2,281,900,000 pounds (approx. 38,000,000 tons), of which corn accounted for 229,000,000 pounds. In 1920 the total figure had fallen to 665,500,000 pounds. The corresponding figure for corn is negligible. For 1925 the total figure was, according to official statements, 1,405,200,000 pounds.

IMPROVEMENT SCHEMES

The question in relation to the improvement of navigable waterways was resumed after the war and, although many big schemes can hardly be expected to materialize, it is none the less true that a large number of far-reaching plans are already in course of being realized, or are ripe for execution.

Rhône-Rhine Navigation.—The navigable waterway which the canalization of the Rhône would establish from Marseilles through Lyons and Geneva (if the French and Swiss governments agreed about the régime for the Lake of Geneva), might be of first-class importance for traffic to Switzerland, and the eventual continuation of this waterway through Switzerland by the canal known as Entreroches (a scheme warmly supported by the Swiss Assn. for Rhône-Rhine Navigation), would increase its importance. This scheme for a navigable waterway between the Rhône and the Rhine through Switzerland seems still immature.

Rhine Navigation.—The second large scheme prepared by the French Government is for the great Alsace canal between Huningue and Strasbourg. This canal, which will serve both for navigation and the supply of water-power, is to follow a course nearly parallel to the Rhine over a distance of about 114 kilometres. The plan involves the erection of a weir across the Rhine bed. Further, eight power stations will be constructed on the canal and two locks placed at each station. The dimensions of this waterway would allow barges of 1,200 tons, normal type on the Upper Rhine above Mannheim. The scheme for this canal required the approval of the Central Commission for Rhine Navigation. After giving its consent to the construction of the first reach of the canal in 1922, the commission in April 1925 approved the scheme for the seven other reaches subject to certain conditions.

Switzerland has prepared a scheme for the regulation of the Rhine between Strasbourg and Basel. This scheme has also been conditionally approved by the Central Rhine Commission, and the work may therefore shortly be put in hand (see RHINE).

Communication from the Rhine to Antwerp.—A clause in the Treaty of Versailles provides for the possible construction of a deep-draught canal from Antwerp to the Meuse and the Rhine, ending in the neighbourhood of Ruhrort. The early execution of this scheme is unlikely because of the considerable expenditure involved, and also owing to the fact that the consent of Holland is necessary. The right solution for the improvement of the communication with Antwerp seems to be an Antwerp-Moerdijk

canal, as was provided for in the Dutch-Belgian Treaty, which was, however, rejected by the First Chamber of the Dutch Parliament. Fresh negotiations have been entered into by the parties concerned and will undoubtedly permit of a satisfactory solution. It seems indicated that the new communication between Antwerp and the Rhine should be navigable for the large Rhine barges, that is to say for vessels up to 3,000 tons.

Meuse Canalization.—In the Netherlands the most important scheme now being carried out is the canalization of the Meuse on Dutch territory, which further involves a junction canal between the Meuse and the Waal and the Juliana canal from Maasbracht southwards, the latter intended to link up the mining centre with the navigable waterways of the country. The canalized Meuse will be navigable for boats of 2,000 tons. Locks 260 metres long will be able to take a tug and two barges of 2,000 tons each. The Meuse-Waal canal will be navigable for boats of the same tonnage.

Completion of Rhine-Vistula System.—In Germany two large schemes are being carried out. The Mittelland canal, which will connect Hanover with the Elbe near Magdeburg, will establish an uninterrupted navigable waterway between the Rhine and the Vistula. This canal will form the last section of the waterway begun with the construction of the Dortmund-Ems canal between 1889 and 1899, followed by the Rhine-Herne canal, opened in 1914, and the Bevergern-Misburg canal constructed during the War. The last-mentioned canal, which is 172 km. long, is without locks. The total length without locks, including certain parts of adjacent canals, is no less than 213 kilometres. The Mittelland canal will be navigable for boats of 1,000 tons. It will cross the Elbe by a bridge, the plans for which have been submitted for the approval of the International Elbe Commission.

Rhine-Main-Danube Connection.—The second important scheme in process of execution is the junction between the Rhine, the Main and the Danube. The idea of linking up the Rhine and the Danube is a very old one. Charlemagne conceived the idea of constructing a canal, traces of which can still be seen. The Ludwig canal, opened in 1846, was only navigable by small boats up to 120 tons and has never been much used. It is anticipated that the area tapped by the Rhine-Main-Danube navigable waterway will exceed that of any other European river and canal system. The scheme involves the canalization of the Main, the construction of lateral canals and of a junction canal between the Main and the Danube, joining up with the latter near Kelheim. It also necessitates the regulation of the Danube between Regensburg and Hofkirchen, and between Passau and the frontier and in addition its canalization over the stretch between Hofkirchen and Passau, that is to say, in the Bavarian Kachlet. The waterway will be navigable for canal barges of 1,200 tons and for Rhine barges up to 1,500 tons. The scheme also provides for the utilization of hydraulic power; in fact, it is the production of electric power that has made the scheme practicable.

Other German Schemes.—Among the other plans for the construction of canals in Germany, such as the Hansa canal, the canal from the Weser to the Main, the Kuesten-Kanal and the junction canal between Neckar and Danube, only the last deserves serious consideration at present. The canalization of the Neckar might be of considerable value for the development of navigation and for the port of Mannheim. At one time it seemed that, mainly for political reasons, opinion in Germany was in favour of constructing the Weser-Main canal (the Weser being the only important river which has escaped internationalization) in order to direct part of the traffic from the Danube to Bremen, after the construction of the Main-Danube canal. The Weser could also carry some of the traffic normally carried by the Rhine and the Elbe. But the changed political situation makes it improbable that this scheme will be put into effect at any early date.

Italian Waterways.—In Italy a canal has been constructed from the Po to Brondolo on the Lagoon of Venice. A canal is also in course of construction from Milan to the confluence of the Adda and the Po, whereby Milan will be linked by waterway to Venice.

Czechoslovakian Waterways.—In Czechoslovakia, besides canalization work on the Elbe and the Moldau and the regulation of the Danube, the Government has carefully considered two canal

schemes, an Elbe-Danube canal and an Elbe-Oder canal navigable for vessels of 1,200 tons. The length of the Elbe-Danube canal would be about 300 kilometres. Its course would follow as far as possible the line of the most important towns. Financial considerations are retarding the execution of these schemes.

Polish Waterways.—At the request of the Polish Government the League of Nations Committee for Communications and Transit appointed three engineers (Case, *United States*, Nijhoff, *Netherlands*, Watier, *France*), to study the plan for a coal canal between the mining district of Upper Silesia and the mouth of the Vistula, and also the general problem of the development of the Polish navigable waterways considered as a whole, in particular the best technical methods for regulating the Vistula and for the construction of the East to West canal. The Committee of Engineers did not recommend the immediate construction of a coal canal, but urged the complete improvement of the Vistula, including a lateral canal from the coal basin to the Cracow district, prolonged by canalization of the river to the confluence of the San, and then, by regulation of the remainder of the river to its mouth. It was further recommended that work should be started on the Warta-Lake Goplo canal and on the great waterway Bug-Prípet. The entire East to West Branch will consist of the canalized Notec, the Bydgoszcz canal, the Brda, the Vistula up to Modlin, the Bug-Narev, the canalized Muchawiec, the improved Royal canal and the regulated Prípet. The latter would link up this waterway with the great navigable system of Russia through the Dnieper.

The Russian System.—The Russian rivers which are naturally navigable have suffered but little from the lack of upkeep in the course of the last 10 years. The proposal to construct the Rostov canal to unite the Volga and the Don may be carried into effect, though there are great technical difficulties in the way of this scheme. Its completion would reduce the cost of transport of oil from Baku, fish from Astrakhan, corn from the valleys of the Volga and the Kama, coal from the Donetz and merchandise from Persia. The importance of the proposed canal is obvious, as the immense system of the Volga, which is navigable for more than 16,000km., will thus be linked up with the Black sea, and the Baltic, Black and Caspian seas will be connected by navigable waterways. There is already a service between Leningrad via the Mariinsky system and the Volga to Astrakhan and thence to the Persian port of Enzeli. The immense territory of Russia may become of capital importance in the future from the point of view of inland waterway communications. The system of waterways is more than 200,000km. in length, of which at present some 40,000 are navigable. The Asiatic Russian system from the Ob-Yenesi mouths to Central Asia and Lake Baikal lies outside the scope of this article.

VALUE OF WATERWAYS

Economic considerations will play a part in decisions that may be taken for the improvement of existing waterways or the construction of new ones. The question will inevitably arise whether a railway would not prove more serviceable than a waterway. The preference will clearly go to whichever mode of transport is cheaper. In comparing the advantages of waterways and railways, we must distinguish between rivers and canals; and we must further discriminate between canals built across flat country and those constructed across land where there are marked differences in level.

Rivers not naturally navigable may generally be rendered navigable by regulation works, such as spur dikes or longitudinal dikes, or by canalization works such as the construction of dams across the bed of the river and locks to enable boats to pass. The forming of large reservoirs in the upper courses of waterways belonging to the basin of a large river may also constitute an excellent means of improving navigability by regulating the flow of water. In this way a greater minimum depth is obtained and the period of navigability during the year is lengthened.

In most cases the cost of building a railway having the same carrying capacity as a river is appreciably higher than the cost of making the river sufficiently navigable. Moreover, the cost of

river-craft having a given loading capacity is less than that of railway rolling stock having the same capacity. Further, the haulage power of a locomotive is only a small fraction of that of a tug. This argument remains true even if a proper use of a waterway involves the execution of improvement works. Moreover, the economic development of the area served by the river leads to a considerable increase in passenger and parcels traffic, for which the railway is necessarily more suitable than the waterway, so that we always find railway lines alongside the river, connecting up the various important centres situated thereon. The argument that a river can compete with a railway holds good even if the traffic does not, strictly speaking, consist of heavy goods, such as ores or coal. The Danube is a case in point; before the World War the volume of traffic on that river amounted to nearly 7,000,000 tons.

The case is different, however, if it is an artificial navigable waterway, *i.e.*, a canal, which has to be built. As a rule such a work is not justified from the economic point of view unless the prospective traffic in heavy goods (ores, coal, building material, cereals and certain other agricultural products) is to amount to several million tons per annum. In order to determine the cost price of transport by canal we have to allow for possible profits and advantages derived from the exploitation of hydraulic power, and accordingly we have to make a distinction between a canal crossing flat country and a canal built in mountainous districts. Many projects for artificial waterways have been rendered feasible by the utilization of water power. Wherever the configuration of the ground has permitted, recent schemes have combined the construction of a navigable waterway with the exploitation of hydro-electric power. The question therefore whether, in any given case, it is preferable from the economic point of view to construct a canal rather than a railway cannot be answered so readily as when the alternatives are a railway and a river; the answer depends upon a very large number of factors.

International Rivers.—A special category of waterways is constituted by those which come under the scope of the Convention on the Régime of Navigable Waterways of International Concern concluded at Barcelona on April 20, 1921. The criteria adopted at Barcelona were the fact of crossing or separating a number of countries, and natural navigability to and from the sea. In addition to the obligations which devolve upon riparian states, particularly in connection with works of upkeep, the Barcelona Convention lays down the principle of freedom of navigation and equality of treatment for all flags.

The objection has sometimes been raised that two different ideas have been confused, namely, the territorial idea and the idea of international traffic. It is clear that if it is in the interest of international traffic that there should be no flag discrimination, this principle applies wherever international navigation is carried on, independent of whether the navigable waterway crosses or separates several States or not.

On the other hand it is only natural that, as regards international rivers, there was a desire to impose certain strict obligations on riparian States in connection with the hydraulic works to be carried out; these obligations, however, should rather be regarded as reciprocal obligations between riparian States. It would seem not impossible by drawing a clear distinction between the territorial idea and the idea of international traffic to lay down, for all navigable waterways on which international traffic can be carried on, contractual provisions similar to those which have been drawn up for maritime ports.

In the application of the Barcelona Statute, the following are declared to be navigable waterways of international concern:

1. All parts which are naturally navigable to and from the sea of a waterway which in its course, naturally navigable to and from the sea, separates or traverses different States, and also any part of any other waterway naturally navigable to and from the sea, which connects with the sea a waterway naturally navigable which separates or traverses different States.

It is understood that:

(a) Trans-shipment from one vessel to another is not excluded by the words "navigable to and from the sea";

(b) Any natural waterway or part of a natural waterway is termed "naturally navigable" if now used for ordinary commercial navigation,

or capable by reason of its natural conditions of being so used; by "ordinary commercial navigation" is to be understood navigation which, in view of the economic condition of the riparian countries, is commercial and normally practicable;

(c) Tributaries are to be considered as separate waterways;

(d) Lateral canals constructed in order to remedy the defects of a waterway of international concern, including its tributaries of international concern, are deemed to be "riparian States."

2. Waterways, or parts of waterways, whether natural or artificial, expressly declared to be placed under the régime of the General Convention regarding navigable waterways of international concern either in unilateral acts or the States under whose sovereignty or authority these waterways or parts of waterways are situated, or in agreements made with the consent, in particular, of such States.

Inquiry into Existing Conditions.—In accordance with a resolution of the Economic Conference of Genoa, which was approved by the Council and Assembly of the League of Nations; the Organization for Communications and Transit decided in 1924 to make inquiries of the various European governments concerned regarding the present situation of inland navigation in their respective territories. For inland water transport in America see the articles UNITED STATES, *Inland Water Ways*; GREAT LAKES, THE; and MISSISSIPPI RIVER; CANALS AND CANALIZED RIVERS.

INLAYING, a method of ornamentation by inserting in one material a substance differing therefrom in colour or composition. The art is practised in the fabrication of furniture and artistic objects in all varieties of wood, metal, shell, ivory, coloured and hard stone, and in compound substances. Forms of inlay include:

Niello (q.v.), is an ancient and much-practised method of inlaying silver and gold with various metals.

Demascening is the inlaying of gold wire in iron or steel.

Mosaic (q.v.) is generally applied to inlay work in hard stone, marble and glass, but the most important class of mosaics—those which consist of innumerable small separate pieces—do not properly come under the head of inlaying.

Pietra dura is a fine variety of inlaid mosaic in which hard and expensive stones—agate, cornelian, amethyst and the like—are used in relief.

Intarsia was originally a true inlay of one or more colours of wood upon a darker or lighter ground, and it is from this form of inlaying that marquetry and other wood inlays were developed.

Inlay and Marquetry.—Inlay is more often confined to woodwork, and the art of decorating the surfaces of furniture or wall panelling with small pieces of wood, ivory, tortoise-shell, etc., that are cut into various designs and set into the body of the surface. The term "inlay" is often confused with and sometimes used for the word "marquetry." Marquetry is composed of pieces of very thin wood, or other material of equal thickness, laid down upon a matrix with glue. Thus marquetry is a veneer process, while true inlay is what the term implies—"a laying in" of one material into another material called the "ground." Marquetry is a later development of the ornamental inlays of wood known by the name of Intarsia, which, although a true inlay as opposed to the thin veneer of marquetry, furnishes many examples wherein the process follows that of marquetry. For example in the cathedral of Ferrara, Italy, the backs of the stalls show the perspective lines of some of the subjects traced upon the ground where the marquetry has fallen off, but none of the "sinkings" would be there if the panels had been executed as true inlays instead of veneers.

Process.—The design for a panel is drawn on paper, the lines being pricked through to underlying sheets to make the necessary number of copies, or the pricked sheet is dusted over with a

coloured powder which passes through the perforations and marks the design faintly on the paper underneath. The pieces of paper are then cut up and stuck on to several pieces of wood which form the design, one whole print being reserved to paste complete on to the ground or field. Each piece may be cut separately, but they are all bound to fit into the complete pattern when this is cut out of the ground, because all are cut from the same prints. In true inlay the pieces to be inserted are cut out of wood $\frac{1}{8}$ to $\frac{1}{4}$ in. thick. The surface into which these separate designs are to be set is carved out the required depth with wood-carver's tools, and the pieces making the design are driven in.

In marquetry two panels are sometimes made of the reverse colourings by sawing through the ground and the veneer at the same time. At one time it was quite a common occurrence to produce two pieces of furniture in which one was brass inlaid in the black, and in the other case the pattern was black inlaid in the brass, thus utilizing what would otherwise have been very costly waste material. Although this method of cutting through two or more pieces of wood clamped together, and simply dropping one piece into the opening made by the other, is not generally considered as fine work, many excellent inlayers like Boulle in the time of Louis XIV., did their inlay work, or marquetry, in just that way. When all the parts have been cut and fitted together face downwards, paper is glued over them to keep them in place, and the ground and the veneer are carefully levelled. The ground is then wetted with glue at a high temperature and the surfaces squeezed between the frames called "cauls" until the glue is hard.

History and Development.—Probably the earliest examples of inlay were found in the Venetian work of the 14th century, when wood was inlaid on ivory boxes. Other materials were used at an early date. One of the most beautiful forms of inlay executed by the Italians was with ivory upon walnut wood or black wood. In the 16th century the Italians made inlays of marble in various colours, and in the 17th century a combination of tortoise-shell and metal was not uncommon.

Most of the examples found in England are importations, either from Holland or France. The reputation of the Dutch *marqueteurs* was so great that Colbert engaged two, Pierre Gale and Vordt, for the Gobelins at the beginning of the 17th century. Jean Macé of Blois, the first Frenchman known to have practised the art, who was at work in Paris from 1644 (when he was lodged in the Louvre) or earlier, till 1672, as a sculptor and painter, learned marquetry in the Netherlands. His daughter married Pierre Boulle, and the greatest of the family, André Charles Boulle, succeeded to his lodging in the Louvre on his death in 1672. The members of this family are perhaps the best known of the French *marqueteurs*. Their greatest triumphs were gained in the marquetry of metal and tortoise-shell combined with beautifully chiselled ormolu mountings. It is thought by many that Boulle carried the work of inlaying too far. The 18th century commode of late Louis XIV. period, of tortoise-shell, mother-of-pearl and coloured ivories inlaid in brass, an example of which may be seen at South Kensington, is characteristic.

The Stuart period produced a good deal of marquetry in England, often pieces of real excellence. Long-case clocks, cabinets, chests of drawers and various other pieces of furniture were subjected to this kind of decoration. A shallower form of marquetry and some solid inlay work were also extensively used in the latter part of the 18th century. With the increase in luxury and display in the 17th and 18th centuries in France and Germany, cabinets and desks became objects upon which extraordinary talent and expenditure were lavished. Perhaps the most beautiful examples of the art in Italy are the panels of choir stalls or sacristy cupboards, though marriage coffer were also often sumptuously decorated in this manner. (F. L. D.)

INMAN, HENRY (1801-1846), American painter, was born in Utica (N.Y.), on Oct. 20, 1801. Apprenticed to the painter John W. Jarvis at the age of 14, he left him after seven years and set up for himself, painting portraits, genre and landscape. He was one of the organizers of the National Academy of Design in New York and its first vice-president (from 1826-32). As a portrait painter he was highly successful both in New York

and Philadelphia, and going to England in 1844, he had for sitters the lord chancellor (Cottenham), the poet Wordsworth, Doctor Chalmers, Lord Macaulay and others. His American sitters included President Van Buren and Chief Justice Marshall. He died in New York city on Jan. 17, 1846.

INN, a right bank tributary of the Danube. It rises in a small lake under Piz Longhino, in the Swiss canton of the Grisons. After flowing for 55 m. through the Engadine, it enters Austria at Martinsbruck, and continues as a swift mountain stream along the Inn Thal as far as Innsbruck where it enters the broader Unter Inn Thal. At Rosenheim it leaves the limestone zone of north Tirol and enters the plateau of Upper Bavaria, across which it flows to join the Danube at Passau. Its chief tributary is the Salzach on which stands the town of Salzburg. (See DANUBE.)

INNATE IDEAS, ideas or intellectual functions which are supposed to be inborn in, or native to, the human mind, as distinguished from those which are "acquired" in the course of experience, or are constructed by the mind on the analogy of experienced objects. The existence of innate ideas formed the subject of acute controversy in the 17th century. Herbert of Cherbury maintained the innate character of certain "common notions," such as substance, equality, etc., and axioms or "eternal truths" like "things equal to the same thing are equal to one another." Descartes likewise upheld the innate status of such ideas as those of God, substance, unity, equality, etc., and of various axioms of geometry, etc. Locke, on the other hand, denies the existence of innate ideas, and expressed his adhesion to the Aristotelian principle that all ideas are derived, directly or indirectly, from sense-experience—*nil est in intellectu quod non prius fuerit in sensu*. He tried to refute Descartes by contending, as he well might, that there is no evidence for the existence of any full-fledged ideas in the minds of new-born infants, and that even savages are deficient in many of the ideas which Descartes considered to be innate in the human mind. Locke, however, had really misunderstood Descartes, who did not maintain that innate ideas are explicit in the human mind from birth, but only that there are in man certain *tendencies* to construct and apply certain ideas when occasion arises.

Man, as Leibnitz urged against Locke, is after all endowed from birth with an intellect so constituted as to function in certain ways in due course—*nil est in intellectu . . . excipere nisi ipse intellectus*. Nobody now shares Locke's view that the human mind at birth is a *tabula rasa*, a blank tablet waiting passively to receive the impressions of the senses. All admit nowadays, indeed emphasize, the existence of certain native tendencies and endowments in the individual mind from birth or even sooner. But the views about their nature or previous history are various. Confining ourselves to such fundamental ideas as the so-called categories (substance, attribute, cause, effect, etc.) there is, on the one hand, the *a priori* view usually associated with the name of Kant (really much older), namely, that they are functionally inherent in the very structure of the mind, and are not derived from experience, because experience itself would be impossible without them. On the other hand, there is the empirical, evolutionary view put forward by H. Spencer, that although such ideas could not have evolved in the limited life-time of an individual, but are hereditary and so native in a sense, yet they may have been acquired from experience in the course of the vast period of the evolution of the human race. (See CATEGORIES, DESCARTES, KANT, LEIBNITZ.) (A. Wo.)

INNERLEITHEN, a police burgh, parish and health resort of Peeblesshire, Scotland, on Leithen Water, near its junction with the Tweed, 6½ m. S.E. of Peebles by the L.N.E. railway. Pop. (1921) 2,403. It seems once to have been known as Horne-huntersland, and to have been mentioned as early as 1159. Its chief industry is the manufacture of tweeds and other woollen goods, which, together with the fame of its medicinal springs, brought the burgh into prominence towards the end of the 18th century. The spa, alleged to be the St. Ronan's well of Scott's novel of that name, has a pump-room, well-house, etc. The town is flanked on the west by the hill fort of Caerlee and on the east by that of the Pirm. Farther east, close to the village of Walker-

burn, are Purvis hill terraces, a remarkable series of earthen banks, the origin and purpose of which are unknown. Traquair house, or palace, on the right bank of the Tweed, is one of the oldest inhabited houses in Scotland, the most ancient portion dating from the 10th century, and including a remnant of the castle.

INNES, JAMES DICKSON (1887-1914), English landscape painter was born at Llanelly (Carmarthen), on Feb. 27, 1887. His mother was of Catalanian descent. He studied art at the Slade school (1905-08) and exhibited for the first time at the New English Art club in 1907. He travelled in France and Spain and exhibited his work at the Chenil gallery in 1910. He then worked with his friend, Augustus John, in Wales. In 1913 he went to Morocco. He died at Swanley on Aug. 22, 1914. His early work was influenced by W. Sickert and Wilson Steer. Later he became a follower of the post-Impressionists, while his last water-colours are in the spirit of J. S. Cotman. The Tate gallery has a number of his water-colours.

INNESS, GEORGE (1825-1894), American landscape painter, was born near Newburgh (N.Y.), on May 1, 1825. Before he was five years of age his parents had moved to New York and afterwards to Newark (N.J.), in which city his boyhood was passed. He would not "take education" at the town academy, nor was he a success as a greengrocer's boy. He had a strong bent towards art, and his parents finally placed him with a drawing-master named Barker. At 16 he went to New York to study engraving, but soon returned to Newark, where he continued sketching and painting after his own initiative. In 1843 he was again in New York, and is said to have passed a month in Gignoux's studio. But he was too impetuous, too independent in thought, to accept teaching; and, besides, the knowledge of his teachers must have been limited. Practically he was self taught, and always remained a student. In 1851 he went to Europe, and in Italy got his first glimpse of real art. He was there two years, and imbibed some traditions of the classic landscape. In 1854 he went to France, and there studied the Barbizon painters, whom he greatly admired, especially Daubigny and Rousseau. After his return to America he opened a studio in New York, then went to Medfield (Mass.), where he resided for five years. A pastoral landscape near this town inspired the characteristic painting "The Medfield Meadows." Again he went abroad and spent six years in Europe. He came back to New York in 1876, and lived there, or near there, until the year of his death, which took place at Bridge of Allan on Aug. 3, 1894, while he was travelling in Scotland. He was a National Academician, a member of the Society of American Artists, and had received many honours at home and abroad. He was married twice, his son, George Inness (b. 1854), being also a painter. Inness was emphatically a man of temperament, of moods, enthusiasms, convictions. He was fond of speculation and experiment in metaphysics and religion, as in poetry and art. Swedenborgianism, symbolism, Socialism, appealed to him as they might to a mystic or an idealist. He aspired to the perfect unities, and was impatient of structural foundations. This was his attitude towards painting. He sought the sentiment, the light, air, and colour of nature, but was put out by nature's forms. How to subordinate form without causing weakness was his problem, as it was Corot's. His early education gave him no great technical facility, so that he never was satisfied with his achievement. His was an original—a distinctly American—mind in art. Most of his American subjects were taken from New York state, New Jersey and New England. His point of view was his own. At his best he was often excellent in poetic sentiment, and superb in light, air and colour. He had several styles: at first he was somewhat grandiloquent in Roman scenes, but sombre in colour; then under French influence his brush grew looser, as in the "Grey Lowering Day"; finally he broke out in full colour and light, as in the "Niagara" and the last "Delaware Water-Gap." Some of his pictures are in American museums, but most of them are in private hands. (J. C. VAN D.)

INNOCENT (INNOCENTIUS), the name of 13 popes and one anti-pope.

INNOCENT I., pope from 402 to 417, was the son of Pope Anastasius I. During his papacy the siege of Rome by Alaric

(408) took place; the pope was, however, absent from Rome on a mission to Honorius at Ravenna at the time of the sack in 410. He maintained and extended the authority of the Roman see as the ultimate resort for the settlement of all disputes; his still extant communications to Victricius of Rouen, Exuperius of Toulouse, Alexander of Antioch and others, as well as his action on the appeal made to him by Chrysostom against Theophilus of Alexandria, are examples of his intervention. He took a decided view on the Pelagian controversy, confirming the decisions of the synod of the province of pro-consular Africa held in Carthage in 416, which had been sent to him. He wrote in the same year in a similar sense to the fathers of the Numidian synod of Mileve who, Augustine being one of their number, had addressed him. He died on March 12, 417, and in the Roman Church is commemorated as a confessor with Saints Nazarius, Celsus and Victor, martyrs, on July 28. His successor was Zosimus.

INNOCENT II. (Gregorio Paparesci dei Guidoni), pope from 1130 to 1143, was originally a Benedictine monk. His ability, pure life and political connections raised him rapidly to power. Made cardinal deacon of Sant Angelo in Pescheria by Paschal II. he was employed in various diplomatic missions. Calixtus II. appointed him one of the ambassadors who made peace with the empire and drew up the Concordat of Worms (1122), and in 1123, with his later enemy Cardinal Peter Pierleoni, he was papal legate in France. On Feb. 13, 1130, Honorius II. died, and on that night a minority of the Sacred College elected Paparesci, who took the name of Innocent II. After a hasty consecration he took refuge with a friendly noble from the supporters of Pierleoni, who was elected pope under the name of Anacletus II. by a majority of the cardinals. Innocent refused to recognize the choice; by June, however, he was obliged to flee to France. Here his title was recognized by a synod called by Bernard of Clairvaux at Étampes.

Similar action was taken in Germany by the synod of Würzburg. In Jan. 1131 Innocent met King Henry I. of England at Chartres, and in March, at Liège, the German King Lothair, whom he induced to undertake a campaign against Anacletus. The German army invaded Italy in Aug. 1132, and occupied all Rome except St. Peter's church and the castle of St. Angelo. Lothair was crowned emperor at the Lateran in June 1133, and Innocent gave him the territories of the Countess Mathilda as a fief, but refused to surrender the right of investiture. Left to himself Innocent again had to flee, this time to Pisa. Here he called a council which condemned Anacletus. A second expedition of Lothair expelled Roger of Sicily (to whom Anacletus had given the title of king in return for his support) from southern Italy, but a quarrel with Innocent prevented the emperor attacking Rome. At this crisis, in Jan. 1138, Anacletus died, and a successor elected by his faction, as Victor IV., resigned after two months. The Lateran council of 1139 restored peace to the church, excommunicating Roger of Sicily, against whom Innocent undertook an unsuccessful expedition. The pope supported Bernard of Clairvaux in his prosecution of Abelard and Arnold of Brescia, whom he condemned as heretics. The remaining years of Innocent's life were taken up by a quarrel with the Roman commune, which had set up an independent senate, and one with King Louis VII. of France, about an appointment. France was threatened with the interdict, but before matters came to a head Innocent died on Sept. 22, 1143, and was succeeded by Celestinus II.

See Herzog-Hauck, *Realencyklopädie*. "Innocenz II.," with full references. Gregorovius, *History of Rome in the Middle Ages*, trans. by Hamilton (1896), vol. iv. part ii. pp. 420-453.

INNOCENT III. (Lando da Sezza), anti-pope (1179-80), sprang from a noble Lombard family. Opponents of Alexander III. tried to make him pope in Sept. 1179. Alexander, however, bribed his partisans to give him up, and imprisoned him in the cloister of La Cava in Jan. 1180.

INNOCENT III. (Lotario de' Conti di Segni), pope from 1198 to 1216, son of Trasimondo, count of Segni, and of Claricia, a Roman lady of the noble family of Scotti, was born at Anagni about 1160. At the University of Paris he laid the foundations of his profound knowledge of the scholastic philosophy; at Bo-

logna he studied canon and civil law. On his return to Rome he became a canon of St. Peter's; he was made subdeacon of the Roman Church by Gregory VIII.; and in 1190 his uncle, Pope Clement III., created him cardinal-deacon of Santi Sergio e Baccho. The election of Celestine III. in the following year withdrew Lotario for a while from the active work of the Curia, the new pope belonging to the family of the Orsini, who were at feud with the Scotti. Lotario, however, employed his leisure in writing several works: *Mysteriorum evangelicæ legis ac sacramenti eucharistiae libri VI.*, *De contemptu mundi, sive de miseria humanæ conditionis*, and *De quadrupartita specie nuptiarum*. Of these only the two first are extant; they show a profound erudition. Yet Lotario was destined to be above all things a man of action, and Innocent III. is remembered, not as a great theologian, but as a great ruler and man of affairs.

On Jan. 8, 1198, Celestine III. died, and on the same day Lotario, though not even a priest, was unanimously elected pope by the assembled cardinals. He took the name of Innocent III. On Feb. 21 he was ordained priest, and next day was consecrated bishop. His first acts were to restore the prestige of the Holy See in Italy, where it had been overshadowed by the power of the emperor Henry VI. The early death of Henry VI. (Sept. 1197) had left Germany divided between rival candidates for the crown, Sicily torn by warring factions of native and German barons. It was, then, easy for Innocent to depose the imperial prefect in Rome itself and to oust the German feudatories who held the great Italian fiefs for the empire. Spoleto fell; Perugia surrendered; Tuscany acknowledged the leadership of the pope; papal *rectores* once more governed the patrimony of St. Peter. Finally, Henry's widow, Constance, in despair, acknowledged the pope as overlord of the two Sicilies, and on her death (Nov. 27, 1198) appointed him guardian of her infant son Frederick. Thus in the first year of his pontificate Innocent had consolidated in the peninsula a secure basis on which to build up his world-power.

The effective assertion of this world-power is the characteristic feature of Innocent's pontificate. Other popes before him—from Gregory VII. onwards—had upheld the theory of the supremacy of the spiritual over the temporal authority; it was reserved for Innocent to make it a reality. In Germany his support of Otto IV. against Philip of Swabia, then of Philip against Otto and finally, after Philip's murder (June 21, 1208), of the young Frederick II. against Otto, effectually prevented the imperial power, during his pontificate, from again becoming a danger to that of the papacy in Italy. Concessions at the cost of the empire in Italy were in every case the price of his support. (See GERMANY: *History*.)

In his relations with the German emperors Innocent acted partly as pope, partly as an Italian prince; his victories over other potentates he won wholly in his spiritual capacity. He forced Philip Augustus of France to put away Agnes of Meran and take back his Danish wife Ingeborg, whom he had wrongfully divorced; compelled Peter of Aragon to forgo his intended marriage with Bianca of Navarre and ultimately (1204) to receive back his kingdom as a fief of the Holy See, and caused Alphonso IX. of Leon to put away his wife Berengaria of Castile, who was related to him within the prohibited degrees, though he pronounced their children legitimate. Sancho of Portugal was compelled to pay the tribute promised by his father to Rome, and Ladislaus of Poland to cease from infringing the rights of the church. The archbishop of Trondhjem was called to order for removing the ban of excommunication from the repentant King Haakon IV., as an infringement of the exclusive right of the pope to impose or remove the ban of the church in the case of sovereigns. Kaloyan, prince of Bulgaria, submitted to Rome, and, in Nov. 1204 received the insignia of royalty from the hands of the papal legates as the vassal of the Holy See.

Meanwhile Innocent promoted the crusade which ultimately, under the Doge Dandolo, led to the Latin occupation of Constantinople. (See CRUSADES.) This diversion from its original object was at first severely censured by Innocent; but an event which seemed to put an end to the schism of East and West came to

wear a different aspect; he was the first pope to nominate a patriarch of Constantinople, and he expressed the hope that henceforth the church would be "one fold under one shepherd." By a bull of Oct. 12, 1204, moreover, Innocent proclaimed the same indulgences for a crusade to Livonia as the Holy Land. The result was the "conversion" of the Livonians (1206) and the Letts (1208) by the crusaders headed by the knights of the Teutonic Order. The organization of the new provinces thus won for the church Innocent kept in his own hands, instituting the new archbishopric of Riga and defining the respective jurisdictions of the archbishops and the Teutonic Knights. Another crusade was that proclaimed by Innocent in 1207 against the Albigenses. All that can be said in his favour is that he acted from supreme conviction; and that he did not use force until for ten years he had tried all the arts of persuasion in vain. (See ALBIGENSES.)

Of all Innocent's triumphs the greatest was his victory over King John of England. The quarrel arose out of a dispute as to the election to the vacant see of Canterbury, which Innocent had settled by nominating Stephen Langton (*q.v.*) over the heads of both candidates. John refusing to submit, Innocent imposed an interdict on the kingdom and threatened him with a crusade; and John was compelled to recognize Langton and to hold England and Ireland as fiefs of the Holy See, subject to an annual tribute (May 1213). For years the pope virtually ruled England through his legates. (See ENGLISH HISTORY and JOHN, king of England.) So great had the secular power of the papacy become that a Byzantine visitor to Rome declared Innocent to be "the successor not of Peter but of Constantine."

Innocent's authority within the church itself exceeded that of his predecessors. The centralization of the ecclesiastical administration at Rome received a great impulse, and the independent jurisdiction of metropolitans and bishops was curtailed. He introduced a system of provisions and reservations, by which he brought the patronage of sees and benefices into his own hands—a system which led later to intolerable abuses. The 12th ecumenical council assembled at the Lateran under his presidency in 1215. It was attended by the plenipotentiaries of the emperor, of kings and of princes, and by some 1,500 archbishops, bishops, abbots and other dignitaries. The business before it, the disciplining of heretics and Jews, and the proclamation of a new crusade, etc., vitally concerned the States represented; yet the function of the great assembly was little more than to listen to and endorse the decretals read by the pope. (See LATERAN COUNCILS.) The great pope died on July 16, 1216, at Perugia, and was succeeded by Honorius III.

Whatever judgment posterity may have passed on Innocent's aims, opinion is united as to the purity of the motives that inspired them and the tireless self-devotion with which they were pursued. "I have no leisure," Innocent once sighed, "to meditate on supermundane things; scarce I can breathe. Yea, so much must I live for others, that almost I am a stranger to myself." His views on the papal supremacy are best explained in his own words. Writing to the patriarch of Constantinople (*Inn. III., lib. ii. ep. 200*) he says: "The Lord left to Peter the governance not of the church only but of the whole world"; and again in his letter to King John of England (*lib. xvi. ep. 131*): "The King of Kings . . . so established the kingship and the priesthood in the church, that the kingship should be priestly, and the priesthood royal (*ut sacerdotale sit regnum et sacerdotium sit regale*), as is evident from the epistle of Peter and the law of Moses, setting one over all, whom he appointed his vicar on earth." In his answer to the ambassadors of Philip Augustus he states the premises from which this stupendous claim is logically developed:—

To princes power is given on earth, but to priests it is attributed also in heaven; to the former only over bodies, to the latter also over souls. Whence it follows that by so much as the soul is superior to the body, the priesthood is superior to the kingship. . . . Single rulers have single provinces, and single kings single kingdoms; but Peter, as in the plenitude, so in the extent of his power is pre-eminent over all, since he is the Vicar of Him whose is the earth and the fullness thereof, the whole wide world and all that dwell therein.

To the emperor of Constantinople, who quoted 1 Peter ii.

13, 14, to the contrary, he replied in perfect good faith that the apostle's admonition to obey "the king as supreme was addressed to lay folk and not to the clergy." The more intelligent laymen of the time were not convinced even when coerced. Even so pious a Catholic as the minnesinger Walther von der Vogelweide, giving voice to the indignation of German laymen, ascribed Innocent's claims, not to soundness of his scholastic logic, but to the fact that he was "too young" (*owê der babest ist ze junc*).

The literature on Innocent III. is very extensive; a carefully analysed bibliography will be found in Herzog-Hauck, *Realencyklopädie* (3rd ed., 1901) s. "Innocenz III." In A. Potthast, *Bibliotheca hist. med. aevi* (2nd ed., Berlin, 1896), p. 650, is a bibliography of the literature on Innocent's writings. In the *Corpus iuris canonici*, ed. Aemilius Friedberg (Leipzig, 1881), vol. ii., pp. xiv–xvii., are lists of the official documents of Innocent III. excerpted in the *Decretales Gregorii IX.* The most important later works on Innocent III. are Achille Luchaire's *Innocent III., Rome et l'Italie* (1904), *Innocent III., la croisade des Albigeois* (ib. 1905), *Innocent III., la papauté et l'empire* (ib. 1906), *Innocent III., la question d'Orient* (ib. 1906); *Innocent III., les royautes vassales du Saint-Siège* (ib. 1908); and *Innocent III., le concile de latran et la réforme de l'église* (1908); Baethgen, *Die Regenschaft Papst Innozenz III. im Königreich Sizilien* (1914); E. W. Meyer, *Staatstheorien Papst Innozenz III.* (1919). *Innocent the Great*, by C. H. C. Pirie-Gordon (1907), contains some useful documents. See also H. H. Milman, *History of Latin Christianity* (1855, etc.), vol. v.; F. Gregorovius, *Rome in the Middle Ages*, translated by A. Hamilton (1896), vol. v. pp. 5–110; J. C. L. Gieseler, *Ecclesiastical Hist.*, trans. by J. W. Hull, vol. iii. (1853), which contains numerous excerpts from his letters, etc. Innocent's works are found in Migne, *Patrologiae Cursus Completus, Series Latina*, vols. ccxiv–ccxvii. For a translation of Innocent's answer to King John on the interdict, and John's surrender of England and Ireland to Innocent, see Gee and Hardy, *Documents illustrative of Church History* (1896), pp. 73 et seq.

INNOCENT IV. (Sinibaldo Fiesco), pope 1243–54, belonged to the noble Genoese family of the counts of Lavagna. Born at Genoa, he was educated under the care of his uncle Opizo, bishop of Parma. After taking orders at Parma, when he was made canon of the cathedral, he studied jurisprudence at Bologna. His first recorded appearance in political affairs was in 1218–19, when he was associated with Cardinal Hugolinus (afterwards Gregory IX.) in negotiating a peace between Genoa and Pisa. In 1223 Pope Honorius III. gave him a benefice in Parma, and in 1226 he was established at the curia as *auditor contradictarum litterarum* of the pope, a post he held also under Gregory IX., until promoted (1227) to be vice-chancellor of the Roman Church. In September of the same year he was created cardinal priest of San Lorenzo in Lucina. He was papal *rector* (governor) of the March of Ancona from 1235 to 1240. On June 25, 1243, he was elected pope by the cardinals assembled at Anagni.

When Innocent was raised to the Holy See the emperor Frederick II. lay under excommunication. Frederick hoped great things from the elevation of a member of an imperialist family; but it was soon clear that Innocent intended to pursue the traditions of his predecessors. Embassies and courtesies were, indeed, interchanged, and on March 31, 1244, a treaty was signed at Rome, whereby the emperor undertook to satisfy the pope's claims in return for his own absolution from the ban. Neither side, however, was prepared to begin to carry out the agreement, and Innocent began to feel unsafe in Rome, where the imperial partisans had the ascendancy. He left Rome, ostensibly to meet the emperor, and from Sutri fled by night on horseback, pursued by the emperor's cavalry, to Civitavecchia, whence he took ship for Genoa and proceeded to Lyons, at that time a merely nominal dependence of the empire. Thence he wrote to Louis IX., asking for an asylum in France; but this Louis cautiously refused. From Lyons Innocent issued a summons to a general council, before which he cited Frederick to appear in person, or by deputy. The council, which met on June 5, 1245, was attended only by partisans of the pope; and though Frederick condescended to be represented by his justiciar, Thaddeus of Suessa, the judgment was a foregone conclusion.

On July 17, Innocent formally renewed the sentence of excommunication on the emperor, and declared him deposed from the imperial throne and that of Naples. Frederick retorted by announcing his intention of reducing "the clergy, especially the highest, to a state of apostolic poverty," and by ordaining punish-

ments for those priests who should obey the papal sentence. Innocent proclaimed a crusade against the emperor and armed his agents, the Franciscan and Dominican friars, with special indulgences for those who should take up the cross against the imperial heretic. At the same time he sought to undermine Frederick's authority in Germany and Italy. In Naples he fomented a conspiracy among the feudal lords; in Germany, at his instigation, the archbishops with a few of the secular nobles in 1246 elected Henry Raspe, landgrave of Thuringia, German king; but the "priests' king" died in the following year, William II., count of Holland, being after some delay, elected by the papal party in his stead.

Innocent's relentless war against Frederick was not supported by the lay opinion of his time. It wrought havoc and misery in Germany, where it increased the already bitter resentment against the priests. The pope's legate was driven from England by threats of personal violence and not even the saintly King Louis IX. of France, though he made several vain attempts to mediate, approved the pope's attitude. The failure of the crusade which, in 1248, he led against the Muslims in Egypt, was ascribed to the deflection of money and arms from this purpose to the war against the emperor. Even the clergy were by no means altogether on Innocent's side; the council of Lyons was attended by but 150 bishops, mainly French and Spanish, and the deputation from England, headed by Robert Grossetête of Lincoln and Roger Bigod, came mainly in order to obtain the canonization of Edmund of Canterbury and to protest against papal exactions. Yet Innocent triumphed. His financial position was from the outset strong, for not only had he the revenue from the accustomed papal dues but he received large sums from the powerful religious orders. At first the war went in Frederick's favour; but the capture of Parma by papal partisans (June 16, 1247) turned the scale. Frederick's camp before Parma (the temporary town of Vittoria) was taken and sacked, the imperial insignia being captured. From this blow the emperor never recovered; he died on Dec. 13, 1250.

Innocent left Lyons for Italy in April 1251. He continued the struggle with Frederick's son and successor, Conrad IV., who in 1252 descended into Italy, reduced the rebellious cities and claimed the imperial crown. Innocent now offered the crown of Sicily in turn to Richard of Cornwall, Charles of Anjou, and Henry III. of England, the last of whom accepted the doubtful gift for his son Edmund. After Conrad's capture of Naples Innocent feared that Rome itself might fall into the hands of the German king. But Conrad died on May 20, 1254, leaving his infant son Conradin under the pope's guardianship. Innocent posed as the champion of the infant king. He held, indeed, to his bargain with Henry III. and exercised his rights over the Sicilian kingdom by nominating his own relations to its most important offices. Finally, when Manfred, who by Frederick's will had been charged with the government of the two Sicilies, felt obliged to acknowledge the pope's suzerainty, Innocent threw off the mask, ignored Conradin's claims, and on Oct. 24 formally asserted his own claims to Calabria and Sicily. He entered Naples on the 27th; but meanwhile Manfred had fled and had raised a considerable force; the news of his initial successes reached Innocent as he lay sick, and hastened his end. He died on Dec. 7, 1254, and was succeeded by Alexander IV.

Innocent IV. is comparable to his greater predecessor Innocent III. mainly in the extreme assertion of the papal claims. In some respects he carried on the high traditions of his great predecessors. He admonished Sancho II. of Portugal to turn from his evil courses and, when the king disobeyed, absolved the Portuguese from their allegiance, bestowing the crown on his brother Alphonso. He established an ecclesiastical organization in the newly converted provinces of Prussia, which he divided into four dioceses; but his attempt to govern the Baltic countries through a legate broke on the opposition of the Teutonic Order, whose rights in Prussia he had confirmed.

It was Innocent IV. who, at the council of Lyons, first bestowed the red hat on the Roman cardinals, as a symbol of their readiness to shed their blood in the cause of the church.

Innocent was a canon lawyer of some eminence. His small

work *De exceptionibus* was probably written before he became pope; but the *Apparatus in quinque libros decretalium*, which displays practical sense and a mastery of the materials, was written at Lyons immediately after the council. His *Apologeticus*, a defence of the papal claims against the empire, has been lost. Innocent was also a notable patron of learning; he encouraged Alexander of Hales to write his *Summa universae theologiae*, did much for the universities, notably the Sorbonne, and founded law schools at Rome and Piacenza.

Innocent's letters, the chief source for his life, are collected by E. Berger in *Les Registres d'Innocent IV.* (3 vols., 1884-87). For English readers the account in Milman's *Latin Christianity*, vol. vi. (3rd ed., 1864) is still useful. Full references will be found in Herzog-Hauck, *Realencyklopädie*, vol. ix. (1901).

INNOCENT V. (Pierre de Champagni or de Tarentaise), pope from Jan. 21 to June 22, 1276, was born about 1225 in Savoy and entered the Dominican order at an early age. He studied theology under Thomas Aquinas, Albertus Magnus and Bonaventura, and in 1262 was elected provincial of his order in France. He was made archbishop of Lyons in 1271; cardinal-bishop of Ostia and Velletri, and grand penitentiary in 1275; and, partly through the influence of Charles of Anjou, was elected to succeed Gregory X. As pope he established peace between the republics of Lucca and Pisa, and confirmed Charles of Anjou in his office of imperial vicar of Tuscany. He was seeking to carry out the Lyons agreement with the Eastern Church when he died. His successor was Adrian V. Innocent V., before he became pope, prepared, in conjunction with Albertus Magnus and Thomas Aquinas, a rule of studies for his order, which was accepted in June 1259, and was the author of several works in philosophy, theology and canon law. He is sometimes referred to as *famosissimus doctor*.

See F. Gregorovius, *Rome in the Middle Ages*, vol. 5, trans. by Mrs. G. W. Hamilton (1900-02); A. Potthast, *Regesta pontif. Roman.* vol. ii. (Berlin, 1875); E. Bourgeois de Bienheur eux Innocent V. (1899); J. E. Borel, *Notice biogr. sur Pierre de Tarentaise* (Chambéry, 1890); P. J. Béthaz, *Pierre des Cours de la Salle, pape sous le nom Innocent V.* (Augustae, 1891); L. Carboni, *De Innocentio V. Romano pontifice* (1894).

INNOCENT VI. (Etienne Aubert), pope from Dec. 18, 1352, to Sept. 12, 1362, was born at Mons in Limousin. He became professor of civil law at Toulouse and subsequently chief judge of the city. Having taken orders, he was raised to the see of Noyon and translated in 1340 to Clermont. In 1342 he was made cardinal-priest of *Sti Giovanni e Paolo*, and ten years later cardinal-bishop of Ostia and Velletri, grand penitentiary, and administrator of the bishopric of Avignon. Innocent revoked the reservations and commendations of his predecessor and prohibited pluralities; urged upon the higher clergy the duty of residence in their sees, and diminished the luxury of the papal court. Largely through the influence of Petrarch, whom he called to Avignon, he released Cola di Rienzo, who had been sent a prisoner in Aug. 1352 from Prague to Avignon, and used the latter to assist Cardinal Alborno, vicar-general of the States of the Church, in tranquillizing Italy and restoring the papal power at Rome.

Innocent caused Charles IV. to be crowned emperor at Rome in 1355, but protested against the "Golden Bull" of the following year, which prohibited papal interference in German royal elections. He renewed the ban against Peter the Cruel of Castile, and interfered in vain against Peter IV. of Aragon. He made peace between Venice and Genoa, and in 1360 arranged the treaty of Bretigny between France and England. In the last years of his pontificate he was busied with preparations for a crusade and for the reunion of Christendom, and sent to Constantinople the celebrated Carmelite monk, Peter Thomas, to negotiate with the claimants to the Greek throne. He instituted in 1354 the festival of the Holy Lance. He was succeeded by Urban V.

The chief sources for the life of Innocent VI. are in Baluzius, *Vitae Pap. Avenion.* vol. i. (Paris, 1693); *Magnum bullarium Romanum*, vol. iv. (Turin, 1859); E. Werunsky, *Excerpta ex registris Clementis VI. et Innocentii VI.* (Innsbruck, 1885). See also L. Pastor, *History of the Popes*, vol. i., trans. by F. I. Antrobus (1899); F. Gregorovius, *Rome in the Middle Ages*, vol. 6, trans. by Mrs. G. W. Hamilton (1900-02); D. Cerri, *Innocenzo Papa VI.* (Turin, 1873); J. B. Christophe, *Histoire de la papauté pendant le XIV^e siècle*, vol. 2 (1853); M. Souchon, *Die Papstwahlen* (Brunswick, 1888); G. Daumet, *Innocent VI. et Blanche*

de Bourbon (1899); E. Werunsky, *Gesch. Kaiser Karls IV.* (Innsbruck, 1892). There is an excellent article by M. Naumann in Hauck's *Realencyklopädie*, 3rd ed.

INNOCENT VII. (Cosimo dei Migliorati), pope from Oct. 17, 1404, to Nov. 6, 1406, was born at Sulmona in the Abruzzi in 1339. He was made papal vice-chamberlain and archbishop of Ravenna by Urban VI., and appointed by Boniface IX. cardinal priest of Sta. Croce in Gerusalemme, bishop of Bologna, and papal legate to England. He was unanimously chosen to succeed Boniface. The election was opposed at Rome by a considerable party, but peace was maintained by the aid of Ladislaus of Naples, in return for which Innocent agreed not to come to terms with the anti-pope Benedict XIII., except on condition that he should recognize the claims of Ladislaus to Naples. Innocent issued at the close of 1404 a summons for a general council to heal the schism, but the council never assembled, for the Romans rose in arms to secure an extension of their liberties, and finally maddened by the murder of some of their leaders by the pope's nephew, Ludovico dei Migliorati, they compelled Innocent to take refuge at Viterbo (Aug. 6, 1405). The Romans, recognizing later the pope's innocence of the outrage, made their submission to him in Jan. 1406. He returned to Rome in March, and, by bull of Sept. 1, restored the city's decayed university. He died on Nov. 6, 1406, and was succeeded by Gregory XII.

Loserth, *Geschichte des späteren Mittelalters* (1903); Theodorici de Nyem, *De schismate libri tres*, ed. by G. Erler (Leipzig, 1890); K. J. von Hefele, *Conciliengeschichte* (1855-74), Bd. 6, 2nd ed.; J. von Haller, *Papsttum u. Kirchenreform* (1903).

INNOCENT VIII. (Giovanni Battista Cibo), pope from Aug. 29, 1484, to July 25, 1492, successor of Sixtus IV., was born at Genoa (1432), the son of Arano Cibo, who under Calixtus III. had been a senator of Rome. Through the favour of Cardinal Calandrini, half-brother of Nicholas V., he obtained from Paul II. the bishopric of Savona. Sixtus IV. translated him to the see of Molfetta, and in 1473 created him cardinal-priest of Sta. Balbina, subsequently of Sta. Cecilia. As pope he addressed a fruitless summons to Christendom to unite in a crusade against the infidels, and concluded in 1489 a treaty with Bayezid II., agreeing in consideration of an annual payment of 40,000 ducats and the gift of the Holy Lance to detain the sultan's fugitive brother Jem in close confinement in the Vatican. Innocent excommunicated and deposed Ferdinand, king of Naples, by bull of Sept. 11, 1489, for refusal to pay the papal dues, and gave his kingdom to Charles VIII. of France, but in 1492 restored Ferdinand to favour. In the bull *Summis desiderantes* (Dec. 5, 1484) he instigated very severe measures against magicians and witches in Germany; he prohibited (1486) on pain of excommunication the reading of the propositions of Pico della Mirandola; he appointed (1487) T. Torquemada to be grand inquisitor of Spain; and he offered plenary indulgence to all who would engage in a crusade against the Waldenses. He sent missionaries under Portuguese auspices to the Congo. An important event of his pontificate was the capture of Granada (Jan. 2, 1492), for which Innocent gave to Ferdinand of Aragon the title of "Catholic Majesty." Innocent died on July 25, 1492, and was succeeded by Alexander VI.

The sources for the life of Innocent VIII. are to be found in L. Muratori, *Rerum Italicarum Scriptores* (1723-51), vol. 3, and in Raynaldus, *a. 1484-92*. See also L. Pastor, *History of the Popes*, vol. 5, trans. by F. I. Antrobus (1898); M. Creighton, *History of the Papacy*, vol. 4 (1901); F. Gregorovius, *Rome in the Middle Ages*, vol. 7, trans. by Mrs. G. W. Hamilton (1900-02); T. Hagen, *Die Papstwahlen von 1484 u. 1492* (Brizen, 1885); S. Riezler, *Die Hexenprozesse* (1896); G. Viani, *Memorie della famiglia Cybo* (Pisa, 1808); F. Serdonati, *Vita e fatti d'Innocenzo VIII.* (Milan, 1829).

INNOCENT IX. (Giovanni Antonio Fachinetti) was born in 1519. He filled the offices of apostolic vicar of Avignon, legate at the council of Trent, nuncio to Venice, and president of the Inquisition. He became cardinal in 1583; and under the invalid Gregory XIV. assumed almost the entire conduct of affairs. His election to the papacy, on Oct. 29, 1591, was brought about by Philip II.

Innocent died on Dec. 30, 1591, and was succeeded by Clement VIII.

See Ciaconius, *Vitae et res gestae summorum Pontiff. Rom.* (1601-02); Cicarella, continuator of Platina, *De Vitis Pontiff. Rom.* (both contemporaries of Innocent); Ranke, *Popes* (Eng. trans., Austin, 1840, etc.), ii. 233 seq. (all brief accounts). (T. F. C.)

INNOCENT X. (Giovanni Battista Pamfili) was born in Rome on May 6, 1574, served successively as auditor of the Rota, nuncio to Naples, legate apostolic to Spain, was made cardinal in 1627, and succeeded Urban VIII. as pope on Sept. 15, 1644. Throughout his pontificate Innocent was completely dominated by his sister-in-law, Donna Olimpia Maidalchini, who made herself thoroughly detested for her inordinate ambition and rapacity. Urban VIII. had been French in his sympathies; but the papacy now shifted to the side of the Habsburgs, and there remained for nearly 50 years. Evidences of the change were numerous: Innocent promoted pro-Spanish cardinals; attacked the Barberini, protégés of Mazarin, and sequestered their possessions; aided in quieting an insurrection in Naples, fomented by the duke of Guise; and refused to recognize the independence of Portugal, then at war with Spain. As a reward he obtained from Spain and Naples the recognition of ecclesiastical immunity. In 1649 Castro, which Urban VIII. had failed to take, was wrested from the Farnese and annexed to the Papal States. The most worthy efforts of Innocent were directed to the reform of monastic discipline (1652). His condemnation of Jansenism (1653) was met with the denial of papal infallibility in matters of fact, and the controversy entered upon a new phase. (See JANSENISM.) Innocent died on Jan. 7, 1655, and was succeeded by Alexander VII.

For contemporary lives of Innocent see Oldoin, continuator of Ciaconius, *Vitae et res gestae summorum Pontiff. Rom.*; and Palazzi, *Gesta Pontiff. Rom.* (Venice, 1687-88) iv. 570 sqq.; Ciampi's *Innoc. X. Pamfili, et la sua Corte* (1878) gives a very full account of the period. Gualdus' (pseud. of Gregorio Leti) *Vita de Donna Olimpia Maidalchina* (1666) is gossipy and untrustworthy; Capranica's *Donna Olimpia Pamfili* (Milan, 1875, 3rd ed.) is fanciful and historically of no value. See also Ranke, *Popes* (Eng. trans., Austin, 1840, etc.), iii. 40 sqq.; v. Reumont, *Gesch. der Stadt Rom.* (1867-70), iii. 2, p. 623 sqq.; Brosch, *Gesch. des Kirchenstaates* (1880) i. 409 sqq.; and the extended bibliography in Herzog-Hauck, *Realencyklopädie*, s.v. "Innocenz X."

INNOCENT XI. (Benedetto Odescalchi), pope from 1676 to 1689, was born at Como on May 16, 1611. He studied law in Rome and Naples, entered the Curia under Urban VIII., and became successively protonotary, president of the Apostolic Chamber, governor of Macerate and commissary of Ancona. Innocent X. made him a cardinal (1647), legate to Ferrara, and, in 1650, bishop of Novara. He was chosen to succeed Clement X. on Sept. 21, 1676. He at once applied himself with great thoroughness to moral and administrative reform. The moral teaching of the Jesuits incurred his condemnation (1679) (see LIGUORI), an act which the society never forgave, and which it partially revenged by forcing, through the Inquisition, the condemnation of the quietistic doctrines of Molinos (1687), for which Innocent entertained some sympathy. (See MOLINOS.)

Innocent's protest against Louis XIV.'s extended claim to gallican rights called forth the famous Declaration of Gallican Liberties by a subservient French synod under the lead of Bossuet (1682), which the pope met by refusing to confirm Louis' clerical appointments. His determination to restrict the ambassadorial right of asylum, which had been grossly abused, was resented by Louis, who defied him in his own capital, seized the papal territory of Avignon, and talked loudly of a schism, without, however, shaking the pope in his resolution. Innocent opposed Louis' candidate for the electorate of Cologne (1688), approved the League of Augsburg, acquiesced in the designs of the Protestant William of Orange, even in his supplanting James II., whom, although a Roman Catholic, he distrusted as a tool of Louis. The great object of Innocent's desire was the repulse of the Turks, and his efforts to that end entitled him to share in the glory of relieving Vienna (1683). Innocent died on Aug. 12, 1689, and was succeeded by Alexander VIII.

The Life of Innocent has been frequently written. See Guarnacci, *Vitae et res gestae Pontiff. Rom.* (1751), i. 105 sqq.; Palazzi, *Gesta Pontiff. Rom.* (Venice, 1690); also the lives by Albrizzi (1695), Buona-

mici (1776), and Immich (1900). Particular phases of Innocent's activity have been treated by Michaud, *Louis XIV. et Innoc. XI.* (1882 sqq., 4 vols.); Dubruel, *La Correspond. . . du Card. Carlo Pio*, etc. (see *Rev. des quest. hist.* lxxv. [1904] 602 sqq.); and Gerin, in *Rev. des quest. hist.*, 1876, 1878, 1886. For correspondence of Innocent see Colombo, *Notizie biogr. e lettere di P. Innoc. XI.* (Turin, 1878); and Berthier, *Innoc. PP. XI. Epp. ad Principes* (1890 sqq.). An extended bibliography may be found in Herzog-Hauck, *Realencyklopädie*, s.v. "Innocenz XI."

INNOCENT XII. (Antonio Pignatelli), pope from 1691 to 1700 in succession to Alexander VIII., was born in Naples on March 13, 1615, was educated at the Jesuit college in Rome, entered upon his official career at the age of 20, and became vice-legat of Urbino, governor of Perugia, and nuncio to Tuscany, to Poland and to Austria. He was made cardinal and archbishop of Naples by Innocent XI., whose pontificate he took as a model for his own, which began on July 12, 1691. His reforms were many and salutary. Among other things he struck at the root of nepotism in a bull of 1692 ordaining that thenceforth no pope should grant estates, offices or revenues to any relative. Innocent put an end to the strained relations that had existed between France and the Holy See for nearly 50 years. He obtained from the French bishops the virtual repudiation of the Declaration of Gallican Liberties. He confirmed the bull of Alexander VIII. against Jansenism (1696); and, in 1699, under pressure from Louis XIV., condemned certain of Fénelon's doctrines which Bossuet had denounced as quietistic. (See *FÉNELON*.) Innocent died June 27, 1700, and was succeeded by Clement XI.

See Guarnacci, *Vitae et res gestae Pontiff. Rom.* (1751), i. 389 sqq.; Ranke, *Popes* (Eng. trans., Austin, 1840, etc.), iii. 186 sqq.; v. Reumont, *Gesch. der Stadt Rom.* (1867-70), iii. 2, p. 640 sqq., and the *Bullarium Innoc. XII.* (1697).

INNOCENT XIII. (Michele Angelo Conti), pope from 1721 to 1724, the son of the duke of Poli, and a member of a family that had produced several popes, among them Innocent III., was born in Rome on May 13, 1655, served as nuncio in Switzerland and Portugal, was made cardinal and bishop of Osimo and Viterbo by Clement XI., whom he succeeded on May 8, 1721. One of his first acts was to invest the emperor Charles VI. with Naples (1722); he protested in vain against the imperial investiture of Don Carlos with Parma and Piacenza. He recognized the Pretender, "James III.," and promised him subsidies conditional upon the re-establishment of Roman Catholicism in England. Moved by deep-seated distrust of the Jesuits and by their continued practice of "Accommodation," despite express papal prohibition (see *CLEMENT XI.*), Innocent forbade the Order to receive new members in China, and was said to have meditated its suppression. This encouraged the French Jansenist bishops to press for the revocation of the bull *Unigenitus*; but the pope commanded its unreserved acceptance. Innocent died on March 7, 1724, and was succeeded by Benedict XIII.

See Guarnacci, *Vitae et res gestae Pontiff. Rom.* (1751), ii. 137 sqq., 381 sqq.; Sandini, *Vitae Pontiff. Rom.* (Padua, 1739); M. v. Mayer, *Die Papstwahl Innocenz' XIII.* (1874); Michaud, "La Fin du Clement XI. et le commencement du pontificat d'Innocent XIII." in the *Internat. Theol. Zeitschr.* v. 42 sqq., 304 sqq.

INNOCENTS' DAY or **CHILDREMAS**, a festival celebrated in the Latin church on the 28th of December, and in the Greek church on the 29th (O.S.) in memory of the massacre of the children by Herod. The Church early regarded these little ones as the first martyrs. It is uncertain when the day was first kept as a saint's day. At first it seems to have been absorbed into the celebration of the Epiphany, but by the 5th century it was kept as a separate festival. In Rome it was a day of fasting and mourning. The boy-bishop (*q.v.*), whose tenure of office lasted till Childermas, had his last exercise of authority then, the day being one of the series of days which were known as the Feast of Fools. Parents temporarily abdicated authority, and in nunneries and monasteries the youngest nun and monk were for the twenty-four hours allowed to masquerade as abbess and abbot. These mockeries of religion were condemned by the Council of Basel (1431). The day is still observed as a feast day and merrymaking for children in Catholic countries. Innocent's Day was ever accounted unlucky, and Louis XI. used to prohibit any State business.

INNS AND INNKEEPERS. An inn is a hostelry, hotel or public house kept for reward, for the lodging and entertainment of travellers or of any who need temporary accommodation. The name is also given, in a specialized sense, to the institutions set apart for the study and practice of the law. (See *INNS OF COURT*.)

Inn signs are thought by Sir Thomas Browne to be of pagan origin, the sun and moon so frequently represented showing a dedication to Apollo or Diana. Later on hagiology superseded the pantheon and the saints in the calendar swung on sign-boards, interspersed with the arms of various noble personages, who having been well treated as they passed that way, allowed the innkeeper to display their escutcheons over his portal. The hanging of an ivy bush above the inn door is of immemorial antiquity and has not entirely fallen into disuse at the present day. The chequers so frequently displayed as an ale house sign was common among the Romans and is depicted in a Pompeian street view presented by Sir William Hamilton to the Society of Antiquaries. As to this sign, a writer in the *Gentleman's Magazine* for 1794 (p. 797) states: "The great Earl Warrenne . . . had an exclusive power of granting licenses to sell beer. That his agent might collect the tax more readily, the door posts were painted in chequers, such being the arms of Warren."

Law Relating to Innkeepers.—The term inn includes both as regards privileges and liabilities any house of public entertainment where beds, food, etc., are furnished to all persons paying for the same, although it may be called a hotel, tavern, public house, temperance hotel or coffee house. Apparently, however, a lodging or boarding house is not an inn. An innkeeper "being in some sort a public servant" has no right to select his guests, or insist on knowing the traveller's name and address, or refuse shelter at any hour of the day or night, provided he has vacant accommodation and the traveller is not obviously objectionable. But an innkeeper is not bound permanently to entertain a guest. By the common law of England an innkeeper is responsible for the personal property of a traveller so long as the relationship of landlord and guest continues between the parties, unless the goods are destroyed by the act of God or the king's enemies, which latter term does not include damage by riot or rebellion. No special contract or agreement is necessary in order to raise this obligation, and the loss of the goods is *prima facie* evidence of the innkeeper's negligence. This liability is possibly a survival of a very necessary precaution in the days when it was no uncommon thing for highwaymen and innkeepers to be in league together. But contributory negligence on the part of the guest may relieve the landlord from his legal liability in case of loss.

This common law liability of an innkeeper (except as regards horses, harness and carriages which term includes motor cars) for the safe custody of the goods of a guest is, however, limited by the Innkeepers Liability Act, 1863, which provides that an innkeeper shall not be liable to a greater amount than £30 for loss of goods, unless the loss is caused by the default or neglect of himself or his servants. But this limitation of liability is contentious only with an exhibit of the first section of the act in a prominent position in the hall or entrance to the inn; and if the innkeeper refuse to receive for safe custody any goods of his guest, he is liable for the loss as at common law. But an innkeeper is not an insurer of the persons or wearing apparel of his guests—when the clothing is in actual use—although he must take reasonable precautions for the safety of travellers using his house. In return for these liabilities the law gives him a lien over his guest's goods for the amount of his bill. This is a particular and not a general lien, and attaches only to the actual goods brought by the guest to the inn and housed by the innkeeper with him. When several guests of one party leave together, the lien extends to the goods of all. The innkeeper is only bound to take ordinary care of goods thus held, but he cannot use them or charge for their storage. By the Innkeepers Act, 1878, if goods have been kept for six weeks they may, after advertisement in one London and one local newspaper, be sold on expiry of one month from the date of such advertisement. Apparently this act applies to Scotland in spite of the provision for advertisement in a London paper (*Green's Encyclopaedia of Scots Law*, 2nd ed. vi. p. 571).

In Scotland the law is in all material particulars the same as in England except that accidental fire is considered *damnum fatale* for which the innkeeper is not liable. He is moreover bound to receive and house the goods of a traveller, other than personal effects, provided they are not very exceptional or dangerous.

In the United States the common law follows that of England, and laws of the various States of the Union have diminished the liability of the innkeeper in much the same manner as in England.

(F. Wr.; W. W. P.)

INNSBRUCK, the capital of the Austrian province of Tirol, is a beautiful town situated at a height of 1,880 ft. in a wide plain formed by the Inn and its right bank tributary the Sill and mainly on the peninsula between these streams. Surrounded by lofty mountains that seem to overhang the town it occupies a site both strategically and commercially important at the junction of the highway from Germany to Italy over the Brenner pass with the great thoroughfare from western Europe to Vienna and the east over the Arlberg pass. As the name implies, this is a famous crossing place of the Inn guarded in Roman time by the station of Veldidena, which was succeeded by the Premonstratensian abbey of Wilten. The town is first recorded by its present name in 1187 and in 1233-1235 it was fortified. About 1420 the Archduke Frederick IV. built a new castle here and the town replaced Meran as the capital of Tirol. Its history has been generally uneventful and it always manifested a strong loyalty to the ruling house of Austria, particularly during the revolution of 1848.

Within the town there is a striking contrast between old and new. The narrow arcaded streets of the old town, with fine old frescoed houses of the 17th and 18th centuries, give place to the regularly built blocks and open spaces of the more modern accretions, yet without disturbing the sense of unity. One of the finest of the older buildings is the Franciscan or Court church (1553-1563), mainly in Italian Renaissance style. Within is the remarkable cenotaph of the emperor Maximilian I. (d. 1519), count of the Tirol from 1490 onwards, a gigantic marble sarcophagus with 28 bronze statues of his ancestors and favourite heroes and 24 marble reliefs depicting scenes from his life. The church contains also a number of other tombs of notable historic figures.

The university of Innsbruck, formally founded in 1677, suspended during 1782-1792 and 1810-1826, was refounded in 1826 and makes the town a centre of intellectual life. Well-staffed and equipped with fine buildings and a library of nearly 400,000 volumes, the university influence spreads far beyond the borders of Tirol and Austria. More than 1,500 students attend its courses, 39% coming from the Tirol, 27% from other parts of Austria and 34% from foreign countries including 2% from the United States of America. There is also a well-stocked museum, the Ferdinandeum, with rich collections, some illustrative of the Tirolean life.

Other interesting and historic buildings and monuments combine with the surrounding scenic and climatic attractions to make Innsbruck a centre for tourists, whereby its functions as the regional capital and market are strengthened. Practically two hundred thousand visitors are catered for annually and their needs form the basis of a large trade in foodstuffs and other necessities of daily life. Improved facilities for travel have swelled this tourist traffic in the 20th century, a fact that is reflected in the growth of the town since 1900 when its population numbered 26,866. By the census of March, 1923, it showed 56,365 and is estimated in 1928 as approaching 70,000, mainly German-speaking and Romanists.

INNS OF COURT AND CHANCERY. The inns of court seated in London, Lincoln's inn, Gray's inn, the Inner and Middle Temple, are voluntary societies, unchartered, unincorporated and unendowed. Their early history is very obscure and the date of their respective foundations cannot be precisely determined. It is quite clear, however, that they were the successors, if not the direct descendants of the early law schools which flour-

ished in the city in the 12th and 13th centuries. There was according to tradition a legal institution in Newgate, called Johnstone's inn; another in Pewter lane and a third in Paternoster row. There was the cathedral school of St. Paul's and St. George's inn in Seacole lane, near the Old Bailey, and there was in all probability a school of some sort attached to the church of St. Mary-le-Bow in Cheapside. Throughout the 12th century men learned in the civil and canon law—mostly churchmen—swarmed across the channel for the express purpose of teaching and practising the law. In the reign of Stephen we hear of Roger of Bec lecturing on the sister laws in the city, a proceeding which the citizens induced the king to prohibit. This is the first hint we get of the struggle between the common lawyers and the church. The civilian lawyers had speedily made themselves masters of the common law, as witness the display of knowledge of English law by Lanfranc in his suit with Odo of Bayeux heard before the Conqueror. Henry II.'s judges, although churchmen, were faithful to the common law in his struggle with the church, and those practising before them were also churchmen, many of whom, says Coke, "that I may use the words of the record, kept schools of law in the city of London and taught such as resorted to them the laws of the realm, taking their foundation of *Magna Carta* and *Carta de Foresta*." In 1164, however, the clergy were forbidden to lecture on natural philosophy and municipal law outside their monasteries, and in 1217 clerks and priests were enjoined not to appear as advocates in the secular courts. In 1234 Henry III. by his writ addressed to the mayor and sheriffs of the city ordered "the suppression of the schools of the laws in the city." What "the laws" were we do not know. The term *leges* was used to mean the civil and canon law, and also the laws of the realm. It was probably used here to mean the latter, since as part of the policy of the church to attract all judicial business into the ecclesiastical courts, the clergy were, by a bull of Innocent IV. in 1254, prohibited from teaching the common law at all. What immediate effect Henry's order had we do not know, but we do know that from 1234 to the accession of his son, the profession of the law was thrown into confusion. Unqualified and unsuitable persons were practising the law, with the result that even the judges became tainted. These judicial scandals culminated in a commission of inquiry instituted in 1289 by Edward I. on his return from the Holy Land, and the punishment of many of the judges and officials of the courts. This was followed up by a second commission empowered to reform the legal profession, which directed that students "apt and eager" should be brought up from the provinces and placed in proximity to the courts of law situate at Westminster. And by the statute *De Attornatis et Apprenticiis* the chief justice of the common pleas and his fellow judges were directed to provide a certain number of serjeants and barristers (to use the modern equivalents) who should attend the courts wherever they might be and have exclusive audience therein. We may confidently assume from a case in the Year Book of 1292 that prior to 1289 there existed in the city some society charged with the duty of educating students for the legal profession and granting degrees which entitled them to plead in the courts. We may also assume that this society or some similar body existed even a century earlier, since in the reign of Henry II. we hear of lawyers styled 'masters,' a title which survives in the masters of the bench of an inn of court. This society then, or perhaps group of societies, was the law faculty, and the practising lawyers were the masters of the faculty, just as in any other mediaeval gild. For the inns of court and chancery, like the colleges and halls of Oxford and Cambridge, are children of the gild. Under this system no one could become a master unless he had sat at the feet of some duly qualified master and until by actual performance of the duties of his profession he had proved to the satisfaction of the masters of the faculty assembled in public his right to be included among them. Thus, just as in the universities students would flock round a well-known professor in some faculty and form part of his household, so in London law students became apprentices of a master of the law faculty—a judge, a serjeant-at-law, or it may be only an apprentice-at-law—and live in his private house or inn, together with his officials and clerks. When

the exodus of the lawyers from the city took place we do not know, but we do know that Henry de Lacy, earl of Lincoln, one of Edward's most trusted ministers, purchased a house in Shoe lane from the Black Friars in 1286. He sat as a royal justice for the trials of the judges and other officials in 1289-92, and apart from these duties transacted a vast amount of other legal business, which, after his death in 1311, continued to be conducted in this house by his son-in-law, the earl of Lancaster. The latter died on the scaffold in 1322 and upon the marriage of his widow with Lestrangle, the property passed to her husband's family.

Lincoln's Inn.—According to Dugdale there was a tradition current amongst the ancient of Lincoln's inn that the earl of Lincoln, "about the beginning of Edward II.'s reign, being a person well affected to the knowledge of the law, first brought in the professors of that honourable and necessary study to settle in this place," i.e., in the present Lincoln's inn. This, however, was at that time the town house of the bishop of Chichester, and continued to be occupied by the bishops of that see until 1442. Williams thinks that the earl's house in Shoe lane constituted the original Lincoln's inn, whilst Baildon maintains that de Lacy brought his company of lawyers to settle in Thavie's inn on the opposite side of the lane, west of St. Andrew's church. This house became the property of John Davy, a chancery clerk, a man of some prominence in Holborn from 1350 till his death in 1387. It is this property which became an inn of chancery and was purchased by Lincoln's inn in 1550. This house has been confused with one adjoining, belonging to another John Davy, an armourer, upon whose death it was sold in 1350 to Sir John de Houton, a baron of the Exchequer, and again in 1366 to two clerks in the chancery, which suggests that this house also became a legal hostel. Whether any or which of these houses was the original Lincoln's inn it is impossible to say, but it has been established by G. T. Turner and Williams that the second Lincoln's inn was situated east of Chancery lane. Between the years 1331 and 1334, Thomas de Lincoln, the king's serjeant, son of Thomas de Lincoln, acquired there properties lying between Staple inn and the Rolls, which after passing through other hands—evidently acting as trustees—became the property of the abbot and convent of Malmesbury. In letters patent dated Oct. 6, 1380, it is described as *totum hospicium vocatum Lyncolns Ymme*, and in 1399 the convent was receiving £8 a year rent which, early in the 15th century, was reduced to 40s. on account of the ruinous condition of the premises. This accounts for the removal of the society after the death of Bishop Read in 1415 to his mansion on the other side of the lane.

The earliest records of Lincoln's inn, the *Black Books*, commence in 1422. The item under date 1437-38 of 40s. for the rent of "Lyncollysyn" is obviously for the old premises of Thomas de Lincoln. The rent of the new premises to the bishop of Chichester at this period was ten marks, which sum continued to be paid until the freehold was conveyed to Richard Kingsmill and his fellow benchers by Edward Suliard in 1580 for the sum of £520. By this time the title of "hospicium" had been dropped and the title was now once more "the society of Lincoln inn." All were "fellows" (*socii*) of the "fellowship" (*societas*), although the term "company" was also used to describe the whole body. The control of the society was vested in the council, which consisted of the masters of the bench. Next in rank came the utter-barristers, those who had been called to the bar, and the inner-barristers or students, so called because at the moots held in the hall of the inn the former sat on the outermost part of the form which represented the bar of the court, and the latter sat inside and between them. Formerly attorneys and solicitors also might be members of the inn. The chief officials were the four governors, who ceased to be elected in 1574 and whose place was taken by the treasurer. The other officers were the autumn and Lent readers, the dean of the chapel, the keeper of the *Black Books*, the marshal, the pensioner, originally the chief official, the butler for Christmas, the steward for Christmas, the master of the revels, the chief butler, the escheator, the chaplain and the servants, the chief of whom was the manciple, mentioned in the city archives of 1417. It is interesting to note that Sir Thomas More's grandfather was chief butler prior to his call in 1470.

He became autumn reader in 1489. The chief butler at this period acted rather as clerk to the council than as butler in the modern sense. He was clearly an educated man. The bishop of Chichester's palace and the chapels of Our Lady and of St. Richard sufficed for the needs of the society for nearly a century. The Bishop's Hall was pulled down in 1491 and the present Old Hall erected in its place in 1506. This has recently been restored to its former state. When this proved insufficient for the growing membership the present New Hall was built in 1843. The present chapel, constructed by Inigo Jones, was completed in 1623. Thavie's inn was sold by the benchers in 1769 and thus erased as a legal institution. The other inn of chancery attached to Lincoln's inn, Furnival's inn, dates from about 1406. In 1817, with the exception of the hall, it was rebuilt. This building, abutting upon Holborn, has since been pulled down, and upon its site arose the present office of the Prudential Insurance Society, the ancient hall being again preserved. Here Charles Dickens was living when the *Pickwick Papers* were published.

Gray's Inn.—The site of Gray's inn formed part of the manor of Portpoole, which became the property of Richard de Chyggwell in 1280. This site passed in 1294 to the dean and chapter of St. Paul's, who let it to Reginald de Grey, chief justice of Chester and first Lord Grey of Wilton. There is little doubt that the judge lived here with his clerks and other officers of his court and law students. The Greys had for a century been connected as officials with both the court of exchequer and the chancery. Gray's inn continued in the de Grey family till the conveyance of the manor of Portpoole by Lord Grey of Wilton to Hugh Denys and Mary his wife and other feoffees, who in 1503 sold the manor to the prior and convent of the charter house at Sheen, from whom the benchers held the inn until the dissolution of the monasteries in 1539 when the rent became due to the Crown. In 1733 the benchers acquired the freehold. The existing records of the inn only commence with the year 1569, but from other evidence there is every reason to believe that so far from Gray's inn being the youngest member of the four inns of court, it is at least of equal antiquity to that of any other inn. In 1370 it was described as *hospicium*, from which we are justified in assuming that prior to this date it was in the occupation of a legal society. We have a list of readers commencing with John Markham 1391 and, out of chronological order, William Skipwith 1355, who was already a serjeant. From a Year Book of Edward III. we learn that "Ingleby having taken an exception at bar, Willby and Skipwith answered that that was never an exception taken in that place, though they had often heard it *entre les apprentices en hostelles*." This would mean that Gray's inn was in existence as a legal society at least as early as 1330 and it is highly probable that the description in the Harleian ms. of Ralph Andrew as a bencher of "Grayes Inne" in 1311 is correct. The constitution and officers of the inn are similar to those of the other inns. When the records open governors had ceased to be elected. The control of the inn was vested in the masters of the bench. The office of pensioner was abolished in 1630, but the name survives in the *Pension Book of Gray's Inn* and in the old and new pension chambers, where the masters of the bench meet for the discussion and transaction of the business of the society and for relaxation. Of the servants of the inn the chief were, in 1570, the steward, the master butler, the priest and the master cook. After the Reformation, the priest gave way to the chaplain, and in 1631 the order of precedence was "the preacher, the chaplain, the steward, the master butler, the master cook, to be allowed such commons as gentlemen: the second butler, the third butler, the fourth butler, the second cooke, the preacher's man, the steward's man, one washpot, two turne broches to be allowed such commons as yeomen are." In addition were the chapel clerk, the laundress, the gardener and the cleaners of the sewers and courts. Whether any of the old hall of the de Greys remains cannot be determined. We know that it was rebuilt or re-edified under the supervision of Nicholas Bacon and Gilbert Gerard in 1556. Restored in recent years to its original state it is a particularly fine specimen of Tudor architecture and may be compared with the Middle Temple hall, which it much resembles, although on a smaller scale. The oak screen is said

to have been presented by Elizabeth. The chapel was certainly in existence prior to 1315, when John de Grey made provision for a chaplain. It was reconstructed or re-edified in 1615 and finally restored in 1893. We hear first of the library in 1555. It was housed in a chamber on the first floor of No. 1 Gray's inn square, over which Francis Bacon, afterwards lord chancellor, was allowed to extend his adjoining chambers. In 1788 the library was moved to the old duchy office, east of the hall, and in 1884 No. 8 South square, where Macaulay once had chambers, was swept away for an extension. To make room for a further extension No. 7 has now disappeared also. The oldest chambers in the inn are those erected in Gray's inn place in 1696.

The inns of chancery affiliated to Gray's inn were Staple inn and Barnard's inn. The former was an inn of chancery in the reign of Henry V., and is probably of far earlier date, since here was held the court of the Staple, where the judges sat on woolsacks. The inn is now the property of the Actuaries Society. Barnard's inn, named after Lionel Barnard who leased it from the dean of Lincoln, became an inn of chancery at least before 1451, when we are told by Stow that as a result of "a tumult to-night the gentlemen of the inns of court and chancery and the citizens . . . the principals of Clifford's inn, Furnival's inn and Barnard's inn were sent prisoners to Hartford castle." Its hall was already in existence at this date. The inn is now the property of the Mercer's company and used as a school.

The Inner and Middle Temples, so far as their history can be traced, have always been separate societies. The first mention of the Middle Temple as a distinct society occurs in a will dated 1404, and of the Temple as an inn of court in the *Paston Letters*, where, under date Nov. 1440, the Inner Temple is spoken of as a college, as is also subsequently the Middle Temple. The Temple had been the seat in England of the Knights Templars, on whose suppression in 1312 it passed with other of their possessions to the Crown, and after an interval of some years to the Knights Hospitallers of St. John of Jerusalem. It now appears that 13 houses built by Roger Blom, formerly *nuncius* of the Templars, in the churchyard, north of the church, were let to certain professors of the common law not later than 1326. Notwithstanding the destruction of the muniments of the Temple by fire or by popular commotion, sufficient testimony is attainable to show that in the reigns of Edward III. and Richard II. the Temple had become the residence of the legal communities which have since maintained there a permanent footing. The two societies continued as tenants to the Knights Hospitallers of St. John until the dissolution of the order in 1539; they then became the lessees of the Crown, and so remained until 1609, when James I. made a grant by letters patent of the premises in perpetuity to the benchers of the respective societies on a yearly payment by each of £10, a payment bought up in the reign of Charles II. In this grant the two inns are described as "the Inner and the Middle Temple or New Temple," and as "being two out of those four colleges the most famous of all Europe" for the study of the law. Excepting the church and the priests' hall at the west end of the hall, nothing remains of the edifices belonging to the Knights Templars, the present buildings having been almost wholly erected since the reign of Queen Elizabeth or since the Great Fire, in which the major part of the Inner Temple perished. The church has been in the joint occupation of the Inner and Middle Temple from time immemorial—the former taking the southern and the latter the northern half. The round portion of the church was consecrated in 1185, the nave or choir in 1240. It is the largest and most complete of the four remaining round churches in England, and is built on the plan of the church of the Holy Sepulchre at Jerusalem. Narrowly escaping the ravages of the fire of 1666, this beautiful building is one of the most perfect specimens of early Gothic architecture in England. In former times the lawyers awaited their clients for consultation in the round church, as similarly the serjeants-at-law were accustomed to resort to St. Paul's cathedral, where each serjeant had a pillar assigned him. The constitution of both societies is similar to those of the other inns, but the meetings of the benchers are in both styled a "parliament," which is further evidence of their antiquity.

The *Inner Temple*, comprehending a hall, parliament chamber, library and other buildings, occupies the site of the ancient mansion of the Knights Templars, which has from time to time been more or less rebuilt and extended, the present handsome range of buildings, including a new dining hall, being completed in 1870. The library owes its existence to William Petyt, keeper of the Tower Records in the time of Queen Anne, who was also a benefactor to the library of the Middle Temple. The greatest addition by gift was made by the Baron F. Maseres in 1825. Of the inns of chancery belonging to the Inner Temple *Clifford's inn* was anciently the town residence of the Barons Clifford, and was demised in 1345 to a body of students of the law. It was the most important of the inns of chancery, and numbered among its members Coke and Selden. At its dinners a table was specially set aside for the "Kentish Mess," though it is not clear what connection there was between the inn and the county of Kent. It was governed by a principal and 12 rulers. *Clement's inn* was an inn of chancery before the reign of Edward IV., taking its name from the parish church of St. Clement Danes, to which it had formerly belonged. Clement's inn was the inn of Shakespeare's Master Shallow, and was the Shepherd's inn of Thackeray's *Pendennis*. The buildings of Clifford's inn survive (1928), but of Clement's inn there are left but a few fragments.

The *Middle Temple* possesses in its hall one of the most stately of existing Elizabethan buildings. Commenced in 1562, under the auspices of Edmund Plowden, then treasurer, it was not completed until 1572, the richly carved screen at the east end in the style of the Renaissance being erected in 1575. The hall, which has been preserved unaltered, has been the scene of numerous historic incidents, notably the entertainments given within its walls to regal and other personages from Queen Elizabeth downwards. The library, which contains about 70,000 volumes, dates from 1641, when Robert Ashley, a member of the society, bequeathed his collection of books in all classes of literature to the inn, together with a large sum of money; other benefactors were Ashmole (the antiquary), William Petyt (a benefactor of the Inner Temple) and Lord Stowell. From 1711 to 1826 the library was greatly neglected; and many of the most scarce and valuable books were lost. The present handsome library building, which stands apart from the hall, was completed in 1861, the prince of Wales (afterwards Edward VII.) attending the inauguration ceremony on Oct. 31 of that year, and becoming a member and bencher of the society on the occasion. He afterwards held the office of treasurer (1882). The mss. in the collection are few and of no special value. In civil, canon and international law, as also in divinity and ecclesiastical history, the library is very rich; it contains also some curious works on witchcraft and demonology. There was but one inn of chancery connected with the Middle Temple, that of *New inn*, which, according to Dugdale, was formed by a society of students previously settled at St. George's inn, situated near St. Sepulchre's church without Newgate; but the date of this transfer is not known. The buildings have now been pulled down.

The King's Inns, Dublin, the legal school in Ireland, corresponds closely to the English inns of court, and is in many respects in unison with them in its regulations with regard to the admission of students into the society, and to the degree of barrister-at-law, as also in the scope of the examinations enforced. Formerly it was necessary to keep a number of terms at one of the inns in London—the stipulation dating as far back as 1542 (33 Henry VIII. c. 3). Down to 1866 the course of education pursued at the King's inns differed from the English inns of court in that candidates for admission to the legal profession as attorneys and solicitors carried on their studies with those studying for the higher grade of the bar in the same building under a professor specially appointed for this purpose—herein following the usage anciently prevailing in the inns of chancery in London. This arrangement was put an end to by the Attorneys and Solicitors Act (Ireland) 1866. The origin of the King's inns may be traced to the reign of Edward I., when a legal society designated Collett's inn was established without the walls of the city; it was destroyed by an insurrectionary band. In the reign of Edward III. Sir Robert Preston, chief baron of the Exchequer, gave up his residence within the city

to the legal body, which then took the name of Preston's inn. In 1542 the land and buildings known as Preston's inn were restored to the family of the original donor, and in the same year Henry VIII. granted the monastery of Friars Preachers for the use of the professors of the law in Ireland. The legal body removed to the new site, and thenceforward were known by the name of the King's inns. Possession of this property having been resumed by the Government in 1742, and the present Four Courts erected thereon, a plot of ground at the top of Henrietta street was purchased by the society, and the existing hall built in the year 1800. The library, numbering over 50,000 volumes, with a few mss., is housed in buildings specially provided in the year 1831, and is open, not only to the members of the society, but also to strangers. The collection comprises all kinds of literature. It is based principally upon a purchase made in 1787 of the large and valuable library of Justice Robinson, and is maintained chiefly by an annual payment made from the Central Fund of the Irish Free State in substitution for the annual payment formerly made from the Consolidated Fund to the society in lieu of the right to receive copyright works which was conferred by an Act of 1801, but abrogated in 1836.

In discipline and professional etiquette the members of the bar in Ireland differ little from their English brethren. The same style of costume is enforced, the same gradations of rank—attorney-general, solicitor-general, king's counsel and ordinary barristers—being found. There are also serjeants-at-law limited, however, to three in number, and designated 1st, 2nd and 3rd serjeant. The King's inns do not provide chambers for business purposes; there is consequently no aggregation of counsel in certain localities, as is the case in London in the inns of court and their immediate vicinity.

The corporation known as the *Faculty of Advocates* in Edinburgh corresponds with the inns of court in London and the King's inns in Dublin (see ADVOCATES, FACULTY OF).

INNUENDO: see LIBEL AND SLANDER.

INOUE, KAORU, MARQUESS (1835–1915), Japanese statesman, was born in 1835, a *samurai* of the Chōshū fief. He was a friend of his fellow-clansman Prince Ito, and they visited England together in 1863, serving as common sailors during the voyage. At that time all travel abroad was forbidden on pain of death, but the veto did not prove deterrent in the face of a rapidly growing conviction that, as a matter of self-protection, Japan must assimilate the essentials of Western civilization. Shortly after the departure of Inouye and Ito, the Chōshū fief, having fired upon foreign vessels passing the strait of Shimonoseki, was menaced by war with the Yedo government or with the insulted powers, and Inouye and Ito, on receipt of this news, hastened home hoping to avert the catastrophe. They repaired to the British legation in Yedo and begged that the allied squadron, then about to sail for Shimonoseki to call Chōshū to account, should be delayed that they might have an opportunity of advising the fief to make timely submission. Not only was this

request complied with, but a British frigate was detailed to carry the two men to Shimonoseki, and, pending her departure, the British legation assisted them to lie *perdu*. Their mission proved futile, however, and Inouye was subsequently waylaid by a party of conservative *samurai*, who left him covered with wounds. This experience did not modify his liberal views, and, by the time of the Restoration in 1867, he had earned a high reputation as a leader of progress and an able statesman.

As foreign minister Inouye had the conduct of the long and abortive negotiations for treaty revision between 1883 and 1886, and in 1885 he was raised to the peerage with the title of count, being one of the first group of *Meiji* statesmen whose services were thus rewarded. Prior to his permanent retirement from office in 1898, he held the portfolios of foreign affairs, finance, home affairs and agriculture and commerce, and throughout the war with Russia he attended all important state councils, by order of the emperor, being also specially designated adviser to the minister of finance. In 1907 he was raised to the rank of marquess. His name will go down in his country's history as one of the five *Meiji* statesmen, namely, Princes Ito and Yamagata, Marquesses Inouye and Matsukata and Count Okuma. He died on Sept. 1, 1915.

INOWRACŁAW (Hohensalza), town of Poland, 21 m. S.W. of Thorn. Pop. (1921) 24,277. It is situated on rising ground above a fertile district and has an agricultural trade. Iron-founding and the manufacture of machinery and chemicals are important. In the vicinity are important salt works and a sulphur mine. Inowracław is mentioned as early as 1185, and in 1772 it passed to Prussia. It passed to Poland after the war of 1914–18.

INQUEST: see CORONER.

INQUISITION, THE. The name given to the ecclesiastical jurisdiction dealing both in the middle ages and in later times with the detection and punishment of heretics and all persons guilty of any offence against Catholic orthodoxy. (Lat. *inquisitio*, an inquiry.) It is incorrect to say that the Inquisition made its appearance in the 13th century complete in all its principles and organs. It was the result of, or rather one step in, a process of evolution, the beginnings of which are to be traced back to the fourth century at least.

Opinions of the Fathers.—During the first three centuries of the Church there is no trace of any official persecution, and the earlier Fathers, especially Origen and Lactantius, reject the idea of it. Constantine, by the edict of Milan (313), inaugurated an era of official tolerance, but from the time of Valentinian I. and Theodosius I. onwards, laws against heretics began to appear, and increased with astonishing regularity and rapidity. Heretics are subjected to exile or confiscation, disqualified from inheriting property, and even, in the case of a few groups of Manichaeans and Donatists, condemned to death; but it should be noticed that these penalties apply only to the outward manifestations of heresy, and not, as in the middle ages, to crimes of conscience. Within the Church, St. Optatus alone (*De schismate Donatistarum*, lib. iii. cap. iii.) approved of this violent repression of the Donatist heresy; St. Augustine only admitted a *temperata severitas*, such as scourging, fines or exile, and at the end of the 4th century the condemnation of the Spanish heretic Priscillian, who was put to death in 385 by order of the emperor Maximus, gave rise to a keen controversy. St. Martin of Tours, St. Ambrose and St. Leo vigorously attacked the Spanish bishops who had obtained the condemnation of Priscillian. St. John Chrysostom considered that a heretic should be deprived of the liberty of speech and that assemblies organized by heretics should be dissolved, but declared that "to put a heretic to death would be to introduce upon earth an inexpiable crime."

The Middle Ages.—From the 6th to the 9th century the heterodox, with the exception of the Manichaean sects in certain places, were hardly subjected to persecution. They were, moreover, rare and generally isolated, for groups of sectaries only began to appear to any extent at the time of the earliest appearances of Catharism. But from the latter part of the 10th century until the beginnings of the 12th there were numerous executions of heretics, either by burning or strangling, in France, Italy,

the Empire and England; and during this period it is not easy to determine what part was taken by the Church and its bishops and doctors in this series of executions. In many cases the people, supported by the crown, were responsible for the death of the heretics; the historians give only the faintest indications of any direct intervention of the clergy, except perhaps for the examination of doctrine. The theory in these matters was at first as uncertain as the practice; in the 11th century one bishop only, Theodwin of Liège (d. 1075), affirms the necessity for the punishment of heretics by the secular arm (1050). His predecessor, Wazo, bishop of Liège (1041-44), had expressly condemned any capital punishment and advised the bishop of Chalons to resort to peaceful conversion. In the 12th century Peter the Cantor¹ protested against the death penalty, admitting at the most imprisonment; and in dealing with the heretics of Cologne, St. Bernard, who cannot be accused of leniency where heterodoxy was concerned, recommended pacific refutation, followed by excommunication or prison, but never the death penalty (see BERNARD, ST., OF CLAIRVAUX).

But it must be noticed that from the opening years of the 12th century date the beginnings of a decided evolution in the canon law, continuing up to the time of Innocent III., which substituted for arbitrary decisions according to circumstances an organized and particularized legislation, in which judgment was given *secundum canonicas et legitimas sanctiones*, Anselm of Lucca and the *Panormia* attributed to Ivo of Chartres reproduced word for word under the rubric *De edicto imperatorum in damnationem hoereticorum*, law 5 of the title *De hereticis* of Justinian's code, which pronounces the sentence of death against the Manichaeans; and we should remember that the Cathari, and in general all heretics in the West in the 11th and 12th centuries were considered by contemporary theologians as Manichaeans. Gratian in the *Decretum* proclaims the views of St. Augustine (exile and fines). From the beginning of the 12th century the death penalty for impenitent heretics was frequently demanded in influential quarters. In 1184 Pope Lucius III. and the emperor Frederick Barbarossa agreed on the penalties of exile, confiscation, demolition of their houses, *infamia*, and loss of civil rights. The usage, then, was already quite clear; but the death penalty had not as yet been inflicted. It was probably Peter II. of Aragon who was the first to decree, in 1197, the punishment of death by burning against the heretics who should not have left his kingdom within a given time. But it was Innocent III. who gave the most powerful impetus to the anti-heretical movement in the secular world by his frequent exhortations (beginning in 1198) to the secular princes (letters of March 25, 1199, and Sept. 22, 1207).

Beginnings of the Inquisition.—From the foregoing it is clear that the Inquisition did not arise out of, and at the time of, the crusade against the Albigenses. These executions *en masse* certainly created a definitive precedent for violent repression, but there was still no regular organization: the council of Toulouse, held in Nov. 1229 by the Roman legate after the treaty of peace, attempted to organize one, and constituted itself the tribunal. But the procedure was still uncertain. The emperor Frederick II. defined his jurisprudence more clearly: from 1220 to 1239, supported by Pope Honorius III., and above all by Gregory IX., he established against the heretics of the Empire in general a legislation in which the penalties of death, banishment and confiscation of property were formulated so clearly as to be henceforth incontestable. Gregory IX. felt his influence, and also that of the Dominican Guala, bishop of Brescia, who had subjected his episcopal town to the full rigour of the imperial laws. The pope no longer hesitated as to the principle or the degree of repression; but introduced new methods of inquiry and judgment: he created out of the material furnished by the mendicant orders, and especially the Dominicans, the monastic inquisition, which was more elastic, more constant in its activities and more numerous than the inquisition by legate, and better disciplined than the episcopal inquisition. In Nov. 1232 the

Dominican Alberic went round Lombardy with the title of *Inquisitor haereticae pravitatis*. In 1231 a similar commission was given to the Dominicans of Friesach and to the terrible Conrad of Marburg, whose zeal in Germany even exceeded the pope's wishes. In 1233 Gregory IX. addressed a letter to the bishops in the south of France, in which he announced his intention of employing the preaching friars for the discovery and repression of heresy. The inquisition was now regularly instituted, but its jurisprudence was elaborated by successive additions or limitations by the force of custom and the detailed prescriptions added by the papal constitutions. The pope's commissioners "in the matter of heresy" at first travelled from place to place. On arriving in a district they addressed its inhabitants, called upon them to confess, if they were heretics, or to denounce those whom they knew to be heretics: a "time of grace" was opened, during which those who freely confessed were dispensed from all penalties, or only given a light penance; while those whose heresy had been openly manifested were exempted from the penalties of death and perpetual imprisonment. But this time could not exceed one month. After that began the inquisition. As soon as their mission was at an end, and heresy was considered to be stamped out, the inquisitors left the country. Later, inquisitorial districts were formed. The seat of the Inquisition in each district was the monastery of the order (Dominican or Franciscan) to which the inquisitors for that part belonged. There was never any special court or prison: the *murus* (prison) was lent to the Inquisition by the ecclesiastical or secular authorities. The maintenance of the prisoners and the duty of providing the prison fell in principle upon the bishops (council of Toulouse, 1229), but they tried to evade it. The kings of France, and in particular Louis VIII., granted subsidies to the inquisitors. For each district the inquisitors were chosen by the provincials of their order, approved or rejected by the pope, and removable by him only. Their discretionary powers were absolute. They conducted their interrogations before two persons (laymen or ecclesiastics) and only pronounced their sentence after consultation with leading men in the district. This was the only protection for the accused. It was in vain that the civil lawyers tried to prove that the secular authorities had a right to see the documents bearing on the case; the Inquisition always succeeded in setting aside these claims. The share taken in the proceedings by the bishops, the accused or their representatives, though admitted in principle, was as a rule merely illusory.

Procedure of the Inquisition.—Bernard Guy (Bernardus Guidonis), Dominican, 1261-1331, one of the earliest and most complete exponents of the theory of the Inquisition, admits distinctly that in its procedure *multa sunt specialia*. The procedure was secret and in the highest degree arbitrary, proceeding *sine strepitu et figura iudicii*, its object being to ascertain not so much particular offences as tendencies: the murderers of the inquisitor Peter Martyr (Dominican, d. 1252) were tried, not as assassins, but as guilty of heresy and adversaries of the Inquisition; and on the other hand, external acts of piety and verbal professions of faith were held of no value. Moreover, the Inquisition was not bound by the ordinary rules of procedure in its inquiries: the accused was surprised by a sudden summons, and as a rule imprisoned on suspicion. All the accused were presumed to be guilty, the judge being at the same time the accuser. Absence was naturally considered as contumacy, and only increased the presumption of guilt by seeming to admit it. The accused had the right to demand a written account of the offences attributed to him, but the names of the witnesses were withheld from him (Innocent IV.; bulls *Cum negocium* and *Licet sicut accepimus*), he did not know who had denounced him, nor what weight was attached by the judges to the denunciations against him. The utmost that was allowed him was the unsatisfactory privilege of the *recusationes divinatrices*, i.e., at his first examination he was asked for the names of any enemies of whom he knew, and the causes of their enmity. Heretics or persons deprived of civil rights (*infames*) were admitted as witnesses in cases of heresy. Women, children or slaves could be witnesses for the prosecution, but not for the defence, and cases are even

¹Pierre de Beauvoisis (?), choir-master (*grand-chantre*) of the university of Paris (1184), bishop of Tournai (1191), of Paris (1196); died as a Cistercian in 1197. He was beatified.

to be found in which the witnesses were only ten years of age. Langhino Ugolini states that a witness who should retract his hostile evidence should be punished for false witness, but that his evidence should be retained, and have its full effect on the sentence. No witness might refuse to give evidence, under pain of being considered guilty of heresy. The prosecution went on in the utmost secrecy. The accused swore that he would tell the whole truth, and was bound to denounce all those who were partners of his heresy, or whom he knew or suspected to be heretics. If he confessed, and denounced his accomplices, relatives or friends, he was "reconciled" with the Church, and had to suffer only the humiliating penalties prescribed by the canon law. If further examination proved necessary, it was continued by various methods. Bernardus Guidonis enumerates many ways of obtaining confessions, sometimes by means of moral subterfuges, but sometimes by a process of weakening the physical strength. And as a last expedient torture was resorted to. The Church was originally opposed to torture, and the canon law did not admit confessions extorted by that means; but by the bull *Ad extirpanda* (1252) Innocent IV. approved its use for the discovery of heresy, and Urban IV. confirmed this usage, which had its origin in secular legislation (*cf.* the Veronese Code of 1228, and Sicilian Constitution of Frederick II. in 1231). In 1312 excessive cruelty had to be suppressed by the council of Vienna. The next step was the torture of witnesses, a practice which was left to the discretion of the inquisitors. Moreover, all confessions or depositions extorted in the torture-chamber had subsequently to be "freely" confirmed.

The procedure was of course not litigious; any lawyer defending the accused would have been held guilty of heresy. The inquiry might last a long time, for it was interrupted or resumed according to the discretion of the judges, who disposed matters so as to obtain as many confessions or denunciations as possible. After the different phases of the examination, the accused were divided into two categories: (1) those who had confessed and abjured, (2) those who had not confessed and were convicted of heresy. There was a third class, by no means the least numerous, namely, those who having previously confessed and abjured had relapsed into error. Next came the moment of the sentence: "there was never any case of an acquittal pure and simple" (H. C. Lea). The formula for full and complete acquittal given by Bernardus Guidonis in his *Practica*, should, he says, never or very rarely be employed. The sentences were solemnly pronounced on a Sunday, in a church or public place, in the presence of the inquisitors, their auxiliaries, the bishops, the secular magistrates and the people. This was the *sermo generalis*. The accused who had confessed were reconciled, and the penalties were then pronounced; these were, in order of severity, penances, fasting, prayers, pilgrimages, public scourging, the compulsory wearing on the breast or back of crosses of yellow felt sewn on to the clothes or sometimes of tongues of red, letters, etc. The inquisitors eventually acquired the right of inflicting fines at discretion. In 1244 and 1251 Innocent IV. reprovved them for their exactions. All these minor penalties could be commuted for payments in money in the same way as absolution from the crusader's vow, and the council of Vienna tried to put an end to these extortions. Beyond these minor penalties came the severer ones of imprisonment for a period of time, perpetual imprisonment and imprisonment of various degrees of severity (*muris largus, muris strictus vel strictissimus*). The *muris strictus* consisted in the deepest dungeon, with single or double fetters, and "the bread and water of affliction"; but the severity of the prison régime varied very much. The *muris largus*, especially for a rich prisoner, amounted to a fairly mild imprisonment, but the mortality among those confined in the *muris strictus* became so high that Clement V. ordered an inquiry to be made into the prison régime in Languedoc, in spite of Bernard Guy's protest against the investigation as likely to diminish the prestige of the inquisitors. After the sentences had been pronounced, the obstinate heretics and renegades were for the last time called upon to submit and to confess and abjure. If they consented, they were received as penitents, and condemned on the spot to perpetual imprisonment;

if they did not consent, they were handed over to the secular arm. When the heretic was handed over to the secular arm the agents of the secular power were recommended to punish him *debita animadversione*, and the form of recommending him to mercy was gone through. In effect, handing over to the secular arm was equivalent to a sentence of death, and of death by fire. Jacob Sprenger, Dominican provincial in Germany (1494) and inquisitor, does not hesitate to speak of the victims *quas incinerari fecimus* ("whom we [the inquisitors] caused to be burnt to ashes"). But we must accept the conclusions of H. C. Lea and Vacandard that comparatively few people suffered at the stake in the mediaeval Inquisition. Between 1308 and 1323, Bernard Guy, who cannot be accused of inactivity, only handed over to the secular arm 42 persons, out of 930 who were convicted of heresy.

Punishment by Confiscation of Goods.—From the point of view of jurisprudence of the Inquisition, the confiscation of the condemned man's property by the ecclesiastical and secular powers is only the accompaniment to the more severe penalties of perpetual imprisonment or death; but from the point of view of its economic history the importance of the confiscation is supreme. The practice originated in the Roman law, and all secular princes had already, in their own interest, recognized it as lawful (Frederick Barbarossa, Decree of Verona; Louis VIII., ordinances of 1226, 1229; Louis IX., ordinance of 1234; Raymond VII. of Toulouse, etc.). In the kingdom of France there was a special official, the *procureur des encours* (confiscation in the matter of heresy), whose duty it was to collect the personal property of the heretics, and to incorporate their landed estates in the royal domain; in Languedoc crying abuses arose, especially under Alphonse of Poitiers. Soon the papacy managed to gain a share of the spoils, even outside the states of the Church, as is shown by the bulls *ad extirpanda* of Innocent IV. and Alexander IV., and henceforward the inquisitors had, in varying proportions, a direct interest in these spoliations. In Spain this division only applied to the property of the clergy and vassals of the Church, but in France, Italy and Germany, the property of all heretics was shared between the lay and ecclesiastical authorities. Venice alone decided that all the receipts of the Holy Office should be handed over in full to the state. Clement V., in his attempted reform and regularization of inquisitorial procedure, endeavoured to reduce the confiscations to a fairly reasonable minimum, and in 1337-38 a series of papal inquiries was held into this financial aspect of the matter. The Assize of Clarendon, the Constitutions of Frederick II. (1232) and of Count Raymond of Toulouse (1234) had also come to a joint decision with the councils on this question. Charles V. of France prevailed upon the papacy to abolish this regulation (1378). Confiscation was, indeed, most profitable to the secular princes, and there is no doubt that the hope of considerable gain was what induced many princes to uphold the inquisitorial administration, especially in the days of the decay of faith. The resistance of the south of France to the Capetian monarchs was to a large extent broken owing to the decimation of the bourgeoisie by the Inquisition and their impoverishment by the extortions of the *encours*. The same was the case in certain of the Italian republics; while in districts such as the north of France, where heretics were both poor and few, the Inquisition did not easily take root, nor did it prove very profitable. These confiscations, the importance of which in the political and economic history of the middle ages was first shown fully by H. C. Lea, were a constant source of uncertainty in transactions of all kinds; there was, for instance, always a risk in entering into a contract in a place where the existence of heretics was suspected, since any contract entered into with a heretic was void. Nor was there any more security in the transmission of inheritances for posthumous trials were frequent; the *Liber sententiarum inquisitionis* of Bernardus Guidonis (1307-23) records sentences pronounced after death against 89 persons during a period of 15 years. But not only was their property confiscated and their heirs disinherited; they were subject to still further penalties. Frederick II. extended to heresy the application of the Roman law disqualifying from holding office, and even included under its operation the children and

grandchildren of the guilty man. Alexander IV. and Boniface VIII. lightened the severity of this law, and removed certain disqualifications, notably in the case of ecclesiastical offices and property.

The sphere of action of the Inquisition was gradually extended by the theologians and casuists until sorcery and magic ranked with doctrinal heresy (see Hansen, *Inquisition, Hexenwahn, u. Hexenverfolgung*, 1900). With regard to Jews, they might profess their religion and observe its rites without being in a state of heresy; they were only heretic when they attacked the Christian faith or community, made proselytes, or returned to Judaism after being converted. But those who practised usury were "suspected of not holding orthodox doctrine as to theft" (Vacandard), and on this account the Inquisition gained a hold on them (the special case of Spain is described on page 381).

TREATMENT OF HERESY

England.—The Inquisition was primarily the instrument for the repression of all kinds of breaches of orthodoxy. Its work in this capacity we will now outline for each of the great countries of mediaeval Christendom. England, whether before or after the establishment of the Inquisition, had few trials for heresy and, particularist in this as in all her religious activity, judged them according to her own discipline, without asking Rome for laws or special judges. But orthodoxy remained almost unimpaired until the time of Wycliffe. Apparently neither the Catharist, Waldensian nor pantheistic heresies gained any footing in Great Britain. The affair of the Templars in France, which was quite political, was repeated in England: Clement V. having ordered their arrest, Edward II., after much hesitation, gave orders to the sheriffs to execute it and then decided that the *ecclesiastical law* should be applied. The papal inquisitors sent to England met with a bad reception, and the pope was obliged to forbid them to use torture, which was contrary to the laws of the kingdom. It was found impossible to establish the Templars' guilt and only canonical penalties were inflicted on them. The rising of the Lollards having alarmed both the church and the state, the article *De haeretico comburendo* was established by statute in 1401, and gained a melancholy notoriety during the religious struggles of the 16th century; it seems to have been not so much a measure for the safeguarding of dogma as a violent assertion of the secular absolutism. It was not till 1676 that Charles II. caused it to be abrogated, and obtained a decision that in cases of atheism, blasphemy, heresy, schism and other religious offences, the ecclesiastical courts should be confined to the penalties of excommunication, removal from office, degradation and other ecclesiastical means of censure, to the exclusion of the death penalty. Scotland was much later than England in giving up persecution and bloodshed; and so late as 1696 a student of medicine aged eighteen named Aikenhead was accused of heresy and hanged in Edinburgh.

France.—The activities of the monastic Inquisition in France lay chiefly in the south. The repression of the Albigensian heresy went on even when its importance had disappeared. The chronicle of the inquisitor Guilhem Pelhisso (d. 1268) shows us the most tragic episodes of the reign of terror which wasted Languedoc for a century. Guillaume Arnaud, Peter Cella, Bernard of Caux, Jean de St. Pierre, Nicholas of Abbeville, Foulques de St. Georges, were the chief of the inquisitors who played the part of absolute dictators, burning at the stake, attacking both the living and the dead, confiscating their property and land, and enclosing the inhabitants both of the towns and the country in a network of suspicion and denunciation. The secular authorities were of the utmost assistance to them in this task; owing to the confiscations, the crown had too direct an interest in the success of the inquisitorial trials not to connive at all their abuses. There were frequent attempts at retaliation, directed for the most part against the inquisitors, and isolated attacks were made on Dominicans; but the work of repression culminated under Bernard Guy, and completed the destruction of Catharism, the appearances of which after the middle of the 14th century are rare. Afterwards the efforts of the Inquisition were directed against the Spirituals, who were

a branch of the Franciscans, and were remote disciples of Joachim, abbot of Floris (*q.v.*), and whom their rigid rule of absolute poverty led, by a reaction against the cupidity of the ordinary ecclesiastics, to repudiate the papal hierarchy. On Feb. 17, 1317 John XXII. condemned all these irregular followers of St. Francis, and the Inquisition of Languedoc was at once set against them. Four *spirituales* were burnt at Marseilles in 1318, and soon the persecution was extended to the Franciscan *beguins* or *tertiarii*, many being burnt about 1320. The Waldenses (*q.v.*) were more difficult to destroy: originally less dangerous to the church than the Cathari, they resisted longer, and their dispersal in scattered communities aided their long resistance.

In the north of France the workings of the Inquisition were very intermittent; for there were fewer heretics there than in the south, and as they were poorer, there was less zeal on the part of the secular arm to persecute them. At its outset, however, the Inquisition in the north of France was marked by a series of melancholy events: the inquisitor Robert le Bougre, formerly a Catharist, spent six years (1233-39) in going through the Nivernais, Burgundy, Flanders and Champagne, burning at the stake in every place unfortunates whom he condemned without a judgment, supported as he was by the ecclesiastical authorities and by princes such as Theobald of Champagne. The pope was forced to put a check on his zeal, and, after an inquiry, condemned him to imprisonment for life. We know that there were inquisitors settled in Île de France, Orléanais, Touraine, Lorraine and Burgundy during the 12th century, but we know next to nothing of what they did. In the 14th century, the Flemish and German heresies of the Free Spirit made their appearance in France, and some executions resulted. But in the 15th century, with the exception of a few condemnations aimed against the Hussites, the Inquisition acted but feebly.

From the middle of the 14th century onward, the *parlement* had taken upon itself the right of hearing appeals from persons sentenced by the Inquisition. And the University again, by its faculty of theology, escaped the jurisdiction of the Inquisition. These two great bodies at the time of the Reformation took the place of the Inquisition in dealing with heresy.

Italy.—In Italy heresy not infrequently took on a social or political character; it was sometimes almost indistinguishable from the opposition of the Ghibellines or the communalist spirit of independence. Lombardy, besides a number of Cathari, contained a certain number of vaguely-defined sects against whom the efforts of the Apostolic Visitors sent by Innocent III. were not of much effect. From the very earliest days of the Inquisition, John of Vicenza, Roland of Cremona and Rassiero Sacchoni directed their persecutions against Lombardy, and especially against Milan. St. Peter Martyr, who was conspicuous for his violence, was assassinated in 1252. On March 20, 1256 Alexander IV. ordered the provincial of the friar preachers of Lombardy to increase the number of inquisitors in that province from four to eight. At Florence both heresy and Ghibellinism were alike crushed by the severities of Fra Ruggieri, and indulgences were promised to all who should aid in the extinction of heresy in Tuscany. Certain districts revolted against this violence, which threatened to devastate Italy as it had devastated Provence; in 1277 Fra Corrado Pagano was killed on an expedition against the heretics of the Vattelline, and two years after the people of Parma rose against the inquisitors. Besides, this reign of terror only raised to a furious pitch the passionate and independent piety of the Italian peoples. The Inquisition had a hard struggle against the successes of Gerard Legarelli, and especially Dolcino (see *APOSTOLICI*), which only came to an end after a long and difficult trial of the adepts of the Messianist sect of Guglielma, some of whom belonged to the noble families of Lombardy. Up till the beginning of the 14th century, however, the power of the Inquisition steadily increased, and at this period Zanghino Ugolini appeared as the most skilful exponent of its theory and procedure. About the same time Charles of Anjou introduced the Inquisition into the Two Sicilies, but it could rarely effect anything there; the religious cohesion of the country was weak, and refugees were sure of safe hiding, both Waldenses and Fraticelli being frequently

harboured there.

Venice always preserved its autonomy as regards the repression of heresy; she was perfectly orthodox, but remained independent of Rome; Innocent IV. sent inquisitors there, but the heretics continued actually to be subject to the secular tribunals. In 1288 a compromise was arrived at, and the papal Inquisition was admitted into the republic, but only on condition that it should remain under the secular power; thus there was established a mixed régime which survived till the last days of the Venetian state. In Savoy the Inquisition constantly carried on severe measures against the Waldenses of the Alps. During the 14th and 15th centuries there was an uninterrupted succession of trials.

As regards the papal states, "it was in the nature of things that, by a confusion of the two personages, the pope should consider all opposition to him *qua* Italian prince as resistance offered to the head of the church, *i.e.*, to the church" (Langlois). The Colonna had a personal animosity against the Gaetani; therefore Boniface VIII., a Gaetano, declared the Colonna to be heretics. Rienzi was accused of heresy for having questioned the temporal sovereignty of the pope at Rome. The Venetians, who in 1309 opposed the annexation of Ferrara by Clement V. to the detriment of the house of Este, were proclaimed heretics and placed under the ban of Christendom. Savonarola was attacked because he interfered with the policy of Alexander VI. at Florence. It was this same desire for the hegemony of Italy which inspired the attitude of the popes throughout the middle ages, causing them to excommunicate, apparently without reason so far as doctrine was concerned, the Visconti of Milan, the Della Scala of Verona, the Maffredi of Faenza, etc., and prompting them to lay under an interdict or preach a crusade against certain rebellious great towns (Clement V. against Venice, John XXII. against Milan).

Germany.—In Germany heresies, especially of a mystical character, were numerous; some of them affected the people, and led to religious and social movements of no little importance. The repression of heresy went on by fits and starts, and the Inquisition was never exercised so regularly in the Germanic as in certain of the Latin countries. At the outset of the 13th century persecutions of the Waldenses and Ortlibarii (followers of Ortlieb of Strassburg, *c.* 1200) took place at Strasbourg; measures were taken locally, until, in 1231, Gregory IX. issued definite instructions to the German prelates with a view to a regular repression of heresy, and gave to Conrad of Marburg full powers to execute them. In Feb. 1234 the Diet of Frankfort decided, in spite of the pope's injunctions, that the destruction of heresy should be entrusted to the ordinary magistrates. Moreover, owing to the struggle between the Empire and the papacy, the German prelates always limited the prerogatives of the papal Inquisition. Marsilius of Padua, the theoretical exponent of the imperial rights, attributes to the secular judge the right and obligation to punish heresy, the priest's rôle being merely advisory. In 1353 Innocent VI. tried to implant the papal Inquisition in Germany once for all; its success was but short, and Urban V.'s attempt in 1362 succeeded little better, in spite of the fact that Charles IV. (edicts of Lucca, June 1369) gave him the support of the secular power. Towards 1372, however, Gregory XI. succeeded in regularizing the exercise of the powers of the papal inquisitors on German soil; and the latter, notably Kerlinger, Hetstede, etc., set to work to destroy the communities of the Beghards (who had developed with extraordinary rapidity), to burn their books, to close those *beguinages* which were under suspicion, and to check mystical epidemics such as those of the "flagellants," "dancers," etc. But these measures provoked protests from the people, the secular magistrates and even the bishops, so that Gregory XI., perceiving that he was face to face with the popular party, invited the bishops to control the inquiries of his own envoys. At the end of the 15th century the two inquisitions were acting concurrently.

Bohemia.—In Bohemia and the provinces subject to it the Waldenses had found their chosen country, and by the middle of the 13th century their propaganda was very flourishing. In 1245 Innocent IV. ordered the bishops to prosecute them with the aid of the secular arm, and in 1257, at the request of King Premysl Ottokar II., Alexander IV. introduced the Inquisition into

Bohemia. But from this date till 1335 inquisitorial missions succeeded one another without effecting any sensible diminution in the material and moral strength of the heresy. The Waldenses had been joined by other sectaries, the Luciferani, and especially the Brethren of the Free Spirit. It was in vain that the bishops of Bohemia and Silesia carried on during the second half of the 14th century an active campaign against heresy; the spirit of criticism which had arisen with regard to the morals, and even to the dogmas of the Church, was already preparing the way for Hussitism.

The Balkan States.—In the regions east of the Adriatic, Catharism, the first communities of which had very probably settled here, was supreme in the time of Innocent III. and Honorius III. The first Dominicans who established themselves in these parts had much to suffer from the aggression of those very heretics whom they had come to convert. Gregory XI., implacable in his persecution of Catharism, preached a crusade against them in 1234, and Bosnia was laid waste by fire and sword. But in spite of these violent measures Catharism only gained strength in the churches of Bulgaria, Rumania, Slavonia and Dalmatia. In 1298 Boniface VIII. tried to organize the Inquisition there, but the project remained fruitless. The attempt was revived in 1323 by John XXII. with doubtful success. The persecutions undertaken in the 14th and 15th centuries merely resulted in binding the Cathari to the invading Turks, with whom they found more tolerance than with the Slav princes converted to Roman orthodoxy.

Spain.—In Spain the papal Inquisition only very slowly gained a footing. Spain had been, in turn or simultaneously, Arian under the Visigoths, Catholic under the Hispano-Romans, Mohammedan by conquest, and under a régime of religious peace Judaism had developed there. After the reconquest its heresies had been of minor importance. At the end of the 12th century Alphonso II. and Peter II. had on principle promulgated cruel edicts against heresy, but the persecution seemed to be dormant. By the bull *Declinante* of May 26, 1232 inquisitors were sent to Aragon by Gregory IX. on the request of Raymond of Penaforte, and by 1237-38 the Inquisition was practically founded. But as early as 1233 King James I. had promulgated an edict against the heretics which quite openly put the Inquisition in a subaltern position, and secularized a great part of its activities. The people, moreover, showed great hostility towards it. In Castile Alphonso the Wise had, by establishing in his *Fuero Real* and his *Siete Partidas* an entirely independent secular legislation with regard to heretics (1255), removed his kingdom from all papal interference. At the opening of the 14th century Castile and Portugal had still no Inquisition. It was not against heresy that the church had to direct its vigilance. A mutual tolerance between the different religions had in fact sprung up, even after the conquest; and for a long time past both the decisions of councils and papal briefs had proclaimed their surprise and indignation at this ominous indifference. Sporadic cases of violent measures against Jews and Mohammedans occurred during the 13th century and increased in frequency and severity during the 14th and 15th centuries. Massacres *en masse* and forced baptisms were carried out, instigated by the clergy. A class of "converted" Mohammedans and Jews arose, and increased after the conquest of the kingdom of Granada and the completion of the conquest by Ferdinand and Isabella, and after the pacification of the kingdoms of Aragon and Valencia by Charles V. The Mohammedans and Jews in these parts were given the choice between conversion and exile. Being of an active nature, and desiring some immediate powers as a recompense for their moral sufferings, the Jewish or Mohammedan *Conversos* soon became rich and powerful. In addition to the hatred of the church, hatred and jealousy arose also among laymen and especially in the rich and noble classes. *Limpieza*, *i.e.*, purity of blood, and the fact of being an "old Christian" were made the conditions of holding offices. And a combination of secular jealousy, national pride, and religious bigotry led to the foundation of an essentially national Inquisition, directed against local heretics, and founded without the help of the papacy. It was created in 1480 by Ferdinand and Isabella.

Sixtus IV. had wished the papal Inquisition to be established after the form of the middle ages; but Ferdinand, in his desire for centralization wished to establish an inquisition which should be entirely Spanish, and entirely royal. Rome resisted, but at last gave way. Sixtus IV., Alexander VI., Innocent VIII., Julius II. and after them all the popes of the 16th century, saw in this secular attempt a great power in favour of orthodoxy, and approved it when established. The Inquisition took advantage of this to claim an almost complete autonomy. The decisions of the Roman Congregation of the Index were only valid for Spain if the Holy Office of Madrid thought good to countersign them; consequently there were some books approved at Rome and proscribed in the peninsula, and some which were forbidden at Rome and approved in the peninsula. The Spanish Holy Office perceived long before Rome the dangers of mysticism, and already persecuted the mystics, especially the *Alumbrados* and afterwards the Molinists, while Rome still favoured them. There was even a financial dispute between the Inquisition and the papacy. The Roman Penitentiary sold exemptions from penalties (involving loss of civil rights), such as prison, the galleys and wearing the *sanbenito*, and dispensations from the crime of *Marrania* (secret Judaism). The inquisitors tried to gain control of this sale, and at a much higher price, and were seconded in this by the kings of Spain, who saw that it was to their own interest. The struggle continued throughout the first half of the 16th century, the Curia finally triumphing, thanks to the energy of Paul III. Since, however, the Inquisition continued to threaten the holders of papal dispensations, most of them found it prudent to demand a definite rehabilitation, in return for payments both to the king and the Inquisition. As a national institution the Inquisition had first of all the advantage of a very strong centralization and very rapid procedure, consisting as it did of an organization of local tribunals (established in all parts of the country) with a supreme council at Madrid, the *Suprema*. The grand inquisitor was *ex officio* president for life of the royal council of the Inquisition.

From the very beginning the papacy strengthened the organization by depriving the Spanish metropolitans, by the bull of Sept. 25, 1487, of the right of receiving appeals from the decisions given jointly by the bishops of the various dioceses, their suffragans and the apostolic inquisitors and by investing the inquisitor-general with this right. And, more than this, Torquemada actually took proceedings against bishops; for example, the accusation of heresy against Don Pedro Aranda, bishop of Calahorra (1498); while the inquisitor Lucero prosecuted the first archbishop of Granada, Don Ferdinando de Talavera. Further, when once the Inquisition was closely allied to the crown, no Spaniard, whether clerk or layman, could escape its power. Even the Jesuits, though not till after 1660, were put under the authority of the Suprema. But the descendants of Moors and Jews, though they were good Christians, or even nobles, were most held in suspicion. A family into which a forced conversion or a mixed marriage had introduced Moorish or Jewish blood was almost entirely deprived of any chance of public office, and was bound, in order to disarm suspicion to furnish agents or spies to the Holy Office.

The Spaniards were very quick to accept the Inquisition to such an extent as to look upon heresy as a national scourge to be destroyed at all costs, and they consequently considered it as a powerful and indispensable agent of public protection. As had happened among the Albigenses, commerce and industry were rapidly paralysed in Spain by this odious régime of suspicion, especially as the *Conversos*, who inherited the industrial and commercial capacity of the Moors and Jews, represented one of the most active elements of the population. Besides, this system of wholesale confiscations might reduce a family to beggary in a single day, so that all transactions were liable to extraordinary risks. It was in vain that the counsellors of Charles V., and on several occasions the Cortes, demanded that the inquisitors and their countless agents should be appointed on a fixed system by the state; the state, and above all the Inquisition, refused to make any such change. The Inquisition preferred to draw its revenues from heresy, and this is not surprising if we think of the economic aspect of the Albigensian Inquisition.

The political aspect of the work and character of the Inquisition had been very diversely estimated; it is a serious error to attribute to it, as has too often been done, extreme ideas of equality, or even to represent it as having favoured centralization and a royal absolutism to the same extent as the Inquisition of the 13th and 14th centuries in Languedoc. "It was a mere coincidence," says H. C. Lea, "that the Inquisition and absolutism developed side by side in Spain." The Suprema did not attack all nobles as nobles; it attacked certain of them as *Conversos*, and the Spanish feudal nobles were sure enough of their *limpieza* to have nothing to fear from it. But it is undeniable that it frequently tended to constitute a state within the state. At the time of their greatest power, the inquisitors paid no taxes, and gave no account of the confiscations effected; they claimed for themselves and their agents the right of bearing arms, and it is well known that their declared adversaries, or even those who blamed them in some respects, were without fail prosecuted for heresy. It was, however, only the Bourbons, who had imbibed Gallican ideas, who by dint of perseverance managed to make the Inquisition subservient to the Crown, and Charles III., "the philosopher king," openly set limits to the privileges of the inquisitors. Napoleon, on his entry into Madrid (Dec. 1808), at once suppressed the Inquisition, and the extraordinary general Cortes on Feb. 12, 1813 declared it to be incompatible with the constitution, in spite of the protests of Rome. Ferdinand VII. restored it (July 21, 1814) on his return from exile, but it was impoverished and almost powerless. It was again abolished as a result of the Liberal revolution of 1820, was restored temporarily in 1823 after the French military intervention under the duc d'Angoulême, and finally disappeared on July 15, 1834, when Queen Christina allied herself with the Liberals. It was not, however, till May 8, 1869 that the principle of religious liberty was proclaimed in the peninsula; and even since then it has been limited by the constitution of 1876, which forbids the public celebration of dissident religions (S. Reinach). In 1816 the pope abolished torture in all the tribunals of the Inquisition. It is a too frequent practice to represent as peculiar to the Spanish Inquisition modes of procedure in use for a long time in the inquisitorial tribunals of the rest of Europe. There are no special manuals, or *practica*, for the inquisitorial procedure in Spain; but the few distinctive characteristics of this procedure may be mentioned. The Suprema allowed the accused an advocate chosen from among the members or familiars of the Holy Office; this privilege was obviously illusory, for the advocate was chosen and paid by the tribunal, and could only interview the accused in presence of an inquisitor and a secretary. The theological examination was a minute proceeding; the "qualificators of the Holy Office," special functionaries, whose equivalent can, however, easily be found in the mediaeval Inquisition, charged those books or speeches which had incurred "theological censures," with "slight, severe or violent" suspicion. There was no challenging of witnesses. The torture, to the practice of which the Spanish Inquisition certainly added new refinements, was originally very much objected to by the Spaniards, and Alphonso X. prohibited it in Aragon; later, especially in the 15th, 16th and 17th centuries it was applied quite shamelessly. But by the end of the 18th century, according to Llorente, it had not been employed for a long time; the *fiscal*, however, habitually demanded it, and the accused always went in dread of it. The punishment of death by burning was much more often employed by the Spanish than by the mediaeval Inquisition.

With the extension of the Spanish colonial empire the Inquisition spread throughout it almost contemporaneously with the Catholic faith. Ferdinand IV. decreed the establishment of the Inquisition in America, and Jimenes in 1516 appointed Juan Quedo, bishop of Cuba, inquisitor-general delegate with discretionary powers. Excesses having been committed by the agents of the Holy Office, Charles V. decreed (Oct. 15, 1538) that only the European colonists should be subject to the jurisdiction of the Inquisition; but Philip II. increased the powers of the inquisitors' delegate and, in 1541 established on a permanent basis three new provinces of the Inquisition at Lima, Mexico and Cartagena. The first *auto-da-fé* took place at Mexico in 1574, the year in which Hernando Cortez died. The Inquisition of Portugal was no less

careful to ensure the orthodoxy of the Portuguese colonies. An Inquisition of the East Indies was established at Goa, with jurisdiction over all the dominions of the king of Portugal beyond the Cape of Good Hope. Finally Philip II. even wished to establish an itinerant Inquisition, and at his request the pope created, by a brief of July 21, 1571, the "Inquisition of the galleys," or "of fleets and armies."

During the 16th and 17th centuries the Inquisition in Spain was directed again Protestantism. The inquisitor-general, Fernando de Valdés, archbishop of Seville, asked the pope to condemn the Lutherans to be burnt even if they were not backsliders, or wished to be reconciled, while in 1560 three foreign Protestants, two Englishmen and a Frenchman were burnt in defiance of international law. But the Reformation never had enough supporters in Spain to occupy the attention of the Inquisition for long. After the *Marranes* the mystics of all kinds furnished the greatest number of victims. Here again we should not lose sight of the tradition of the mediaeval Inquisition; the mysticism of the Beghards, the Brethren of the Free Spirit and the innumerable pantheist sects had been pitilessly persecuted by the inquisitors of Germany and France during the 14th and 15th centuries. The Illuminati (*alumbrados*), who were very much akin to the mediaeval sectaries, and the mystics of Castile and Aragon were ruthlessly examined, judged and executed. Not even the most famous persons could escape the suspicious zeal of the inquisitors Valdés and Melchior Cano. St. Ignatius de Loyola was twice imprisoned at the beginning of his career; St. Theresa was accused of misconduct, and several times denounced; one of her works, *Conceptos del amor divino*, was prohibited by the Inquisition, and she was only saved by the influence of Philip II. Countless numbers of obscure visionaries were accused of Illuminism and perished. From its earliest appearance Molinism was persecuted with almost equal rigour. Molinos himself was arrested and condemned to perpetual imprisonment (1685-87), and during the 18th century, till 1781, several Molinists were burnt. The Inquisition also attacked Jansenism, freemasonry (from 1738 onwards; cf. the bull *In eminenti*) and "philosophism," the learned naturalist José Clavijo y Faxarcho (1730-1806), the mathematician Benito Bails (1730-97), the poet Tomas de Iriarte, the ministers Clavijo Ricla, Aranda and others being prosecuted as "philosophers." Subject also to the tribunal of the Holy Office were bigamists, blasphemers, usurers, sodomites, priests who had married or broken the secrecy of the confessional, laymen who assumed ecclesiastical costume, etc.

Two features of the Spanish Inquisition are especially noteworthy: the prosecutions for "speeches suspected of heresy" and the censure of books. The great scholar Pedro de Lerma, who after fifty years at Paris (where he was dean of the faculty of theology) had returned to Spain as abbot of Compluto, was called upon in 1537 to abjure eleven "Erasmian" propositions, and was forced to return to Paris to die. Juan de Vergara and his brother were summoned before the Inquisition for favouring Erasmus and his writings, and detained several years before they were acquitted. Fray Alonso de Virues, chaplain to Charles V., was imprisoned on an absurd charge of depreciating the monastic state, and was only released by the pope at the instance of the emperor. Mateo Pascual, professor of theology at Alcalá, who had in a public lecture expressed a doubt as to purgatory, suffered imprisonment and the confiscation of his goods. The censure of books was established in 1502 by Ferdinand and Isabella as a state institution. All books had to pass through the hands of the bishops; in 1521 the Inquisition took upon itself the examination of books suspected of Lutheran heresy. In 1554 Charles V. divided the responsibility for the censorship between the Royal Council, whose duty it was to grant or refuse the *imprimatur* to manuscripts and the Inquisition, which retained the right of prohibiting books which it judged to be pernicious; but after 1527 it also gave the licence to print. In 1547 the Suprema produced an Index of prohibited books, drawn up in 1546 by the university of Louvain; it was completed especially as regards Spanish books, in 1551, and several later editions were published. Moreover, the *revisores de libros* might present themselves in the name of the Holy Office in any private

library or bookshop and confiscate prohibited books. In 1558 the penalty of death and confiscation of property was decreed against any bookseller or individual who should keep in his possession condemned books. The censure of books was abolished in 1812.

BIBLIOGRAPHY.—A critical bibliography was drawn up by P. Fredericq in the preface to the French translation (1900) of H. C. Lea's important work: *History of the Inquisition in the Middle Ages* (3 vols., 1888). See also J. Havet, *L'Hérésie et le bras séculier au moyen âge jusqu'au XIII^e siècle* in the *Oeuvres complètes*, vol. ii. (1896); Ch. V. INSANITY. This term ordinarily connotes more or less severe unsoundness of mind. Though its loose usage is almost synonymous with mental disease, scientifically the term should only be applied to the mental condition of an individual who, through socially inefficient conduct, has to be placed under supervision and control. The mind is the mechanism by means of which we adapt adequately to our environment and when, through its derangement, conduct is exhibited which the community looks upon as evidence of disease and as implying irresponsibility, the individual concerned is said to be insane and the law steps in to certify him as such. Strictly speaking, then, insanity is really a social and legal term and not medical. Mental illness is a broad concept which may include very efficient members of society. No satisfactory definition can therefore be arrived at, since it would be necessary to define what we mean by sanity, which would involve us in equal difficulties.

It is unnecessary to dwell upon the mystical conceptions of insanity which were held in the middle ages, and it will be sufficient to note that it was only towards the close of the 18th century that this sphere of mental disorder was scientifically studied. This was a period in which materialism flourished and research devoted to the anatomy and physiology of the brain gave the workers reason to believe that the nature and causes of insanity would before long be discovered, since the advance of knowledge in the structure and functioning of the central nervous system was progressing at a rapid rate. A school of thought therefore held sway which founded insanity upon a physiological basis and endeavoured to base all pathology in terms of organic change in the brain. Although the great value of this method cannot be gainsaid, there is ample evidence that other aspects of approaching the problem of insanity are essentially necessary. Of late years another school has advanced the belief that the majority of cases of insanity are psychogenic in origin and that even where gross physical disease has been the exciting factor, that the symptoms can only be adequately understood at the psychological level. Others, again, prefer to take a wider view-point still and regard insanity in the light of biological or psycho-biological reactions. Modern psychological knowledge would lead us to believe that the understanding of much of the subject is made clearer when we regard it in the light of instinctive forces conflicting with environment and resulting in a failure of adjustment. The mental symptoms cannot be rightly spoken of as a disease but as types of reaction through the effort on the part of the individual to meet conditions. For the detailed theories of such a conception, the writings of Freud, Jung, Adler and Adolf Meyer should be consulted. The researches of Freud in this direction are of paramount importance and have largely revolutionized many of our ideas on psycho-pathology. The materialistic school would hold that though in many states of insanity no observable structural changes are found, they exist all the same, only they are such that our im-

perfect methods cannot detect them, and in time they will be discovered. At present we have insane conditions divided into those that are regarded as functional and those that are organic. In the former we have mania, melancholia and paranoia, and some would include dementia praecox. The psychogenic school would argue that though mental disease may arise secondarily to physical disorder, the symptoms are psychological reverberations of that disorder and the body of an individual must be regarded as environmental to the ego. In an integrated organism, though the basis of the wrong functioning lies in the physical sphere, some of the effects are manifested at the psychological level. The symptoms, then, are expressions of the personality, and however much we may stress the bodily aspect, that can in no way explain the content of a delusion or an hallucination. The fact that some individuals may take alcohol to the extent of producing severe physical disease without affecting the mind, and others will fall victims to insanity through its use, proves that psychic factors cannot be left out of calculation. The many structural changes which are found in certain forms of insanity should be reviewed as probably secondary to a perverted mentality. The bodily effects of emotion are well known and it can easily be surmised that long continued emotional stress should in time be followed by organic change. During the World War we had ample evidence of this. Mental reactions must be looked upon as reactions of the whole integrated organism which cannot be the expression of any one part of it. As McDougall says, mind has a nature and a structure and functions of its own which cannot be fully and adequately described in terms of structure of the brain and its processes. If this be true, as he thinks, it does not seem logically impossible that the nature of the mind itself may be disordered or impaired or defective. It seems, then, that we must steer clear of belonging to one or other of the extreme camps when we view the nature of insanity, but take a very wide vista which will embrace the study of the individual, his personal and racial history, his environment, and his physical and mental structure.

The causes of insanity will be predisposing and exciting. The former will be those conditions resident within the individual which will render him liable to suffer thus when certain factors are super-added, and the latter are those circumstances which precipitate the mental disturbance.

Predisposing Causes.—(1). *Heredity.* It has to be admitted that few scientific data are before us to establish on any firm basis our knowledge of the inheritance of mental instability. Though there is no doubt as to the enormous importance of this factor, it is certain that in the past the use of this influence has often been a cloak for ignorance and that the effects of early environment and faulty education of the instincts and emotions have not been adequately valued. Most of the statistical work on the subject is of little worth. Human families do not easily lend themselves to genetic study and much is founded on hearsay. Fallacies have arisen because no differentiation has been made between the different varieties of insanity, and the results have been taken as absolute, and are not compared with similar investigations with the family history of normal people. The chief investigations in which these fallacies have been avoided would bring us to the following conclusions: A hereditary taint is present in the relatives of 70% of mentally sound people; of 77% of insane. Of these it affects the distant relatives of the former more than of the latter, but the parents of the latter more than those of the former. Insanity is present in the parent once out of every 30 healthy people, once out of every five insane. Senile dementia, apoplexy, drug habits are all rarer in the parents of insane persons than in those of healthy, while dipsomania and character anomalies are twice as common in the parents of the former. So that hereditary taint is far commoner in normal people than is usually supposed, and an insanity taint is of importance only when present in the parents. It seems that the absence of an hereditary taint makes the occurrence of insanity much less probable than the presence of it makes the occurrence probable. In some cases of insanity heredity is of special importance, e.g., paranoia, manic-depressive insanity, while in others

it is of little or no importance, e.g., general paresis, toxic insanities, etc. Direct heredity is usually pure, that is an epileptic parent tends to have an epileptic child. Transformation is relatively rare. It is not thought that consanguinity or inbreeding has any ill-effects unless the stock is already tainted; then, of course, the chances of transmission are correspondingly increased. Studies on heredity on Mendelian lines (*see MENDELISM*) are inconclusive, but there is some amount of evidence of interest concerning feeble-mindedness, epilepsy, manic-depressive insanity and dementia praecox. In all such studies there is lacking some method of determining what are the fundamental units that can be transmitted by heredity. It is probable that these will be found to be not actual diseases, or even definite predispositions to such, but factors that can develop into either insanity or other conditions (character anomalies, criminality, genius, etc.) according to the interaction of environmental influences.

(2). *Civilization.* It is amongst the most highly civilized that insanity is most prevalent. In the process of evolution, life in general becomes more complex, adaptation more difficult, mental conflict more in evidence. The insane, too, are found with greater frequency in the congested centres of population where the struggle for existence is at its greatest height. The percentage of insanity is greater among the unmarried than the married.

(3). *Sex and Age.* The total incidence of insanity differs but slightly in the two sexes. In the male the effects of alcohol, and syphilis, and general stress tend to balance the special strains of pregnancy, and the change of life in women. The greatest liability to such mental disorder exists between the ages of 30 and 40, but it must be realized that there are more people living in the general community of this age. Considering the number of insane in each decade compared to the total population of the same age, it will be found that the liability practically progressively increases from 20 to 80 years of age.

(4). *Climate.* The only effect of climate is mainly that of supplying conditions which make exhaustion and infection more liable. Malaria, enteric fever and dysentery are responsible for most of the insanity attributed to climatic conditions.

(5). *Physiological Epochs.* At the periods of puberty, adolescence, child-bearing, the climacteric in women and the senium in man, there are special chemical, bodily and mental changes which render the individual more prone.

Exciting Causes.—(1). *Toxic Poisons—Exogenous or introduced from without.* Alcohol in the past has been said to be responsible for much insanity, but recent and more careful investigation would tend to show that this causation has been grossly exaggerated and that really only a small proportion are due directly to this agent. The taking of this drug is very often more a symptom of mental disease than its cause, and, if in any way causative, it is often only so in a contributory way. Alcohol is a narcotic, and by lessening inhibition over the higher centres of judgment and control, any psychopathic tendency is released and appears on the surface. It is, therefore, this tendency to be psychopathic which is the important factor in determining whether or not a person will become insane, and not especially the amount of alcoholism. That the mental factor underlying alcoholism is of great significance has been shown by Bevan Lewis, who found that the least intemperate communities had the highest rate of pauperism and insanity, while the most intemperate communities had the lowest rate. That is, when prosperity was greatest and funds for intemperance were available, poverty and mental stress were least and insanity was less prevalent. F. Mott pointed out that insanity does not keep pace with the incidence of alcohol, and in his large experience he found cirrhosis of the liver very rare in asylums; so that we may infer that most individuals will tolerate any amount of alcohol up to extensive physical disease, without becoming insane and that this only occurs where there are other important factors present.

Other exogenous chemical poisons which may be productive of insanity are opium (morphine), cocaine, and metallic salts of mercury, lead and arsenic. Much more important are those *toxins due to bacterial infection*. *Syphilis* stands out in this respect prominently. When inherited, its effects may severely retard men-

tal development, and when acquired, it may bring about general paralysis, which constitutes 5% to 15% of the total admissions to our mental hospitals. Indirectly, too, it may contribute to the inception of other forms of insanity. Almost any infection may produce insanity in a predisposed individual. The mental reactions occurring in the acute stage of infection are most commonly of a delirious nature, but the subsequent form of insanity will vary according to the personality. Tuberculosis, enteric fever, malaria, and influenza are frequently responsible. Of late years some investigators have laid great stress on infected foci somewhere in the body being causative of different insane states. With this idea in their mind, careful search for such are made in the teeth, tonsils, nasal sinuses, stomach, bowel, genito-urinary passages; and in women, the womb with its appendages. The teeth and tonsils are said to be the commonest sites, and in the hands of the more enthusiastic advocates of this conception, wonderful recovery results are claimed when these infective foci are eliminated. Research of others has not confirmed these findings, and there is grave reason for doubting that any such one factor, and that a physical one, can be alone responsible for such a complex mental state as that of insanity. The great importance, however, of removing possible sources of general infection is always to be borne in mind. *Endogenous chemical poisons* or auto-intoxication have also been presumed to be causative factors, and those of most consequence were thought to originate from the gastro-intestinal tract and as a result of chronic kidney disease. Though in some cases such agents may contribute a causative share, there is no reason for thinking they have any specific value.

(2). *Injuries*. Direct injuries to the head may cause structural lesions of the brain and be the immediate cause of some form of insanity, while more indirect injuries, such as concussion from falls, may also be the starting point of a mental disorder.

(3). *Bodily diseases* may play a part in the production of insanity through the interference they bring about in nutrition, circulation and fatigue.

(4). *Exhaustion* or overwork has been commonly supposed to be a cause, and during the World War a certain type of insanity developed by soldiers on active service was officially designated as "exhaustion psychosis." Though prolonged mental or physical strain often seems to be the precursor of a severe mental breakdown, it is probable that exhaustion *per se* without other and more important adjuvant factors will seldom originate an insane state. The excessive fatigue is frequently a symptom, and if in any way contributory, it must be regarded as one link in a series.

(5). *Mental*. Any severe mental stress may excite insanity when the predisposition exists. Commonly, the mental factor involves some situation which the individual cannot face, and it may be said that in this difficulty he takes refuge in a world of unreality. Domestic trouble, financial worries, deaths of those who are near and dear, sexual problems, are the usual sources of stress met with. Sudden and horrible shocks may act similarly. This psychogenic aspect of insanity has been much studied of late years, and holds a wide field to-day which strenuously opposes the views of the materialistic school.

Classification of Insanity.—Though it is true that different symptoms of insanity tend to arrange themselves into groups, we must bear in mind that the clinical pictures described under their special headings are not by any means clear-cut entities; they are not diseases in the strict sense of the term, but types of reaction. Yet, for descriptive purposes, some classification is needed, and though no classification is entirely satisfactory, the following will best meet our requirements:

- (1) Manic-depressive insanity
- (2) Dementia praecox (Schizophrenia)
- (3) Paranoia group

Characterized by psychical symptoms. No constant changes in brain yet established. Best understood by employment of psychological conception

- (4) Imbecility and idiocy
- (5) Senile dementia

Characterized by qualitative defect of mental functions. Generally accompanied by observable defect or changes in the brain

- (6) Toxic insanity
- (7) General paralysis of the insane
- (8) Organic brain disease
- (9) Epileptic insanity

Diseases of the brain invariably or mostly accompanied by mental symptoms.

(Since we are dealing only with insane states and not mental disorder the neuroses and psycho-neuroses such as neurasthenia [q.v.], anxiety and compulsion neuroses and hysteria are not included.)

General Symptoms of Insanity.—It must be borne in mind that any of the symptoms enumerated, taken by themselves, are not necessarily evidence of an insane condition, but that they only have such an indication when taken in conjunction with each other, when studied in their individual setting and in comparison with the previous expressions of the personality. Again, it must be stressed that though they may indicate mental disorder, it is the factor of conduct that renders the case insane or not. Certain symptoms are more or less particularly associated with special forms of insanity.

General Behaviour.—Some change in this direction is usually the earliest indication noted by friends and relations. This may relate predominantly to the habits, moods, activities or content of speech. The capacity to work, the ability to adapt to circumstances, and the usual respect for the conventions of society, may likely be affected. Alcohol may be unduly indulged in, personal cleanliness and general care of the self neglected, while the character as a whole may undergo transformation. We may have a general over-activity, which commonly is not directed consistently towards a definite goal, and when severe may lead to violence and destructiveness. This is a prominent symptom of mania. On the other hand there may be great difficulty and slowness of voluntary movement, which is specially evinced in melancholia. Movements may be stereotyped and oft-repeated, automatic, just opposite to what we should expect, or impulsive. Curious postures may be taken up, and bizarre mannerisms shown. The stream of speech may be affected similarly. This may be greatly voluble, slow and difficult, or there may be mutism, irrelevance, incoherence.

Disorder of the emotions will be mainly evidenced by an exaggerated sense of well-being, elation or exaltation on the one hand or the reverse picture of gloom and severe depression. The morbidity of these states will accrue from the fact that they are not warranted by the condition of the individual or his surroundings. These extreme emotions are mostly noted in one or other of the phases of manic-depressive insanity. Emotional deterioration, or apathy, is particularly seen in dementia praecox. Anxiety, morbid anger, suspicion, and general instability of the emotions are other frequent abnormalities in this sphere.

Disorders of the content of thought are usually prominent, and a *delusion* is regarded as specially important by the law and laity as evidence of insanity. Such false beliefs may be sane or insane. We may regard them as insane when three characteristics concerning them are found. First, they are evidently untrue, highly improbable, or manifestly impossible. Second, they cannot be corrected by any appeal to reason. Thirdly, they are out of harmony with the individual's education and environment. Nevertheless, sometimes a false belief may be an insane delusion without showing any of these characteristics. Delusions may be very varied, but those of persecution and grandeur are perhaps the most frequent. They may be fixed or changeable; they may or may not affect conduct.

The *process of thinking* itself may be greatly modified. There is difficulty in thinking; much pre-occupation with one idea; thoughts seem stolen; they are obsessive; or everything in the environment is taken personally (ideas of reference).

Disorders of perception may affect any sense. They may be in the form of illusions which are inaccurate perceptions of something really and actually perceived, or hallucinations which have no sensory foundation in the environment, and are created by perverted functioning of the mind. On rare occasions hallucinations occur in normal people. Many can be explained on a purely mental basis, while others have an organic interpretation and are based on physiological disturbances such as toxic states. Auditory hallucinations are the most common, and usually are of the nature of voices. Their content is of great importance in the study of the

patient, and generally are in consonance with the delusions entertained. Most frequently the voices are derogatory and accusatory. Visual hallucinations are mostly noted in toxic forms of insanity. Those affecting smell, taste and touch are of much less frequent occurrence. Psychic or pseudo-hallucinations seem to occupy a position midway between imagination and the fully developed form of hallucination. There is not the same conviction of their external reality, and yet it is believed by the patient that they are brought about by some external agency. Hypnagogic hallucinations are those which occur in the state between sleeping and waking, and these have not the same morbid value. The sensations from the muscles, joints and internal organs may be affected and give rise to curious delusional ideas.

Disorders of orientation imply a lack of appreciation of three aspects of the environment, either simply or together—that of time, space and personal relations. These are not infrequent in severe forms of insanity, and are commonly noted in the confusional conditions of delirium and toxic states.

Disorders of memory will either be complete or partial absence of memory (amnesia) which may only concern past events or be progressive and continuous; false recollections (paramnesia), when the insane patient relates with conviction and detail events which never took place; and excessive retention of memories (hyperamnesia), which occurs in certain insane states.

Disorders of attention may involve the inability to fix the attention for any length of time in one direction (distractability), as seen typically in mania. Where this is in excess there is liable to arise an insufficiency of perception so that orientation is rendered defective. Enfeeblement of the power of voluntary attention is one of the most characteristic signs of dementia (a gradual weakening of the intellectual faculties). In other insane states there may be complete absorption of attention on one or more groups of ideas, which render the individual so self-absorbed that the surroundings are not attended to, and often not seen at all.

Various *disturbances of consciousness* may be manifested. Sleep may be abolished, lessened or increased. The last named is uncommon and is usually associated with brain disease or some general toxæmia. In certain insane patients such as maniacs there exists a marvellous capacity to withstand more or less prolonged sleep deprivation. Trance-like sleep may be noted in other types. In stupor the patient makes little or no response to any stimulus, and such a condition may, when severe, last for lengthy periods. Lastly, we may have symptoms pointing to definite *disorders of the personality*. There may be *depersonalization* when the individual feels that he is no longer himself, or that he no longer exists, or there is the last uncommon condition in which a patient believes himself to be some other person and may act on that belief. In certain severe insane states there may be a gradual disintegration of the personality, which leaves the victim without any of the acquired cultural traits, and only possessing his primitive functions. We can now give some description of the various types of insane conditions met with according to the classification already set forth.

Manic-depressive Insanity.—These disorders which were previously known as mania and melancholia were embraced by Kraepelin under this one heading, as he believed that they were both symptomatic of one morbid process. There is always the liability to the recurrence of attacks, and in these either the manic or the melancholic phase may manifest itself. Kretschmer, of late, in his study of morphological types has concluded that his "pyknic" type, which is characterized by middle height, rounded figure, a short, broad face on a short, massive neck, and a fat paunch protruding from a deep vaulted chest, is the type of individual who would tend to develop this particular form of insanity, if any. Certainly there is a type of personal disposition which is more apt to be thus attacked than others, and one refers to the person who is inordinately optimistic and bright, or, on the other hand, is gloomy and worries over trivialities. Manic-depressive insanity is, therefore, constitutional, and can best be understood from a psycho-pathological standpoint. The deep-seated constitutional origin is marked by its hereditary taint, and by the fact that the attacks are frequently noted for their apparent

lack of cause. Usually, however, some difficulty in the individual's life is found as a precipitating factor.

The *manic-phase* manifests itself by three main symptoms—elation, flight of ideas and general hyperactivity of mind and body. In the mildest type (hypomania) we note these symptoms in slight degree, but the efficiency of the individual is greatly reduced and alcoholic indulgence and delinquent conduct is often seen. In acute mania the symptoms are severe, speech may be so flighty as to be incoherent, and some disorientation is likely to be present. Delusions often occur, but are changeable and ridiculous in character. In the main they will be grandiose in type, but false ideas of persecution may be evinced. Activity of mind and body is constant, little if any sleep is indulged in, food not attended to, so that signs of exhaustion and loss of flesh become marked. Such a patient may be boisterous, destructive and violent. The feeling of exaltation is extreme, and irritation and anger are easily aroused when thwarted. Simple and evanescent hallucinations are often noted. In its most extreme degree this manic phase may be delirious in its severity, and complicated by a septic blood state, brought about by physical injuries.

In the *depressive phase* we note exactly the opposite symptoms of great depression, difficulty in thinking and under-activity of mind and body. Here again we may speak of three grades of severity. In the mildest the individual often realizes his invalidism. He moves and speaks slowly, seems incapable of effort, and sees everything as through a glass darkly. In *acute melancholia* the symptoms are much more pronounced. The depression is profound and delusions of self-accusation referring to sin, poverty and being "lost" are in evidence. Hypochondriacal ideas, such as their bowels being stopped up or their brains decayed, are frequent. The personality may seem to the patient to be transformed, and hallucinations consonant with their delusions also occur. In the severest type there is stupor, and the patient lies in bed inert, with much clouding of consciousness, the victim of horrible delusions and hallucinations.

Manic-depressive insanity may last a variable period, but, though recovery is usually the rule, a recurrence of attacks is highly likely. The interval between such attacks may progressively lessen. Certain cases may remain chronic. Any patient with any state of melancholia much be regarded as a potential suicide, and cared for accordingly.

There is a form of insanity termed *involutional melancholia* which is closely related to manic-depressive insanity, but which occurs at the period of involution, i.e., about 50 years of age. The symptoms are mainly similar to those in the depressive phase of manic-depressive insanity, but there is a greater tendency for the delusions to be hypochondriacal, and there is usually more or less restlessness and anxiety. Hence the old term "agitated melancholia." Fifty per cent make a satisfactory recovery.

Dementia-præcox.—This (more lately termed schizophrenia) is a form of insanity which most usually appears about puberty and adolescence in which heredity seems to play a marked rôle. Recent studies would tend to show that a type of personality, the "shut-in" character (shy and seclusive), is more liable than others to develop this mental disorder. Kretschmer isolates special physical types which he regards as predisposed in this direction. The cause of the condition is highly debatable. It is thought by some to have its root in auto-intoxication, and Mott related it to endocrine disorder especially affecting the sex glands. Focal sepsis is regarded as the most important factor by Cotton of America. Other psychiatrists view the origin from a purely psychological or biological point of view. Bleuler looks upon the disease as a splitting of the personality, while Adolf Meyer believes that it is not a disease but forms of reaction which are the outcome of progressive mal-adaptations of the individual to his environment. Jung draws attention to buried complexes. Which ever view is taken, there seems to be a mental or physical lack of potentiality for development, and the individual is "stranded on the rock of puberty." An exciting factor is often apparently absent, or physical or mental worries or shocks may be a precipitating cause. Though the onset may be acute, in the majority of instances it develops insidiously over a long period of months or

even years. Peculiarities of thought and action finally blossom into insanity. The symptoms seem highly unnatural, and an observer feels quite out of touch with a dementia praecox patient. The most prominent symptom is that of apathy and indifference, and there is a great lack of co-ordination between feeling and intellect which indicates a deep-seated mental change. The patient is fully oriented, his memory is good, but there is a dreamy attitude, with lack of attention and interest. Sudden silly, and seeming causeless outbursts of laughter are frequent. The personality changes so that the habits get slovenly, untidy and dirty. Ideas of reference, illusions, delusions and hallucinations are always present. All sorts of oddities of manner, attitude and speech may be noted, while the judgment becomes so deteriorated that there is no conception by the patient of the seriousness of his disorder or position. Four forms of dementia praecox are ordinarily described; simple dementia, hebephrenia, catatonia and a paranoid form.

In the *simple type* the development is insidious for years. Early on we note dreaminess, or falling off of interest, and an impoverishment of the personality. The individual becomes moody, unsocial, irritable and less and less able to undertake any responsibility or apply himself to anything but a simple task. Many tramps and ne'er-do-wells come into this category.

In *hebephrenia* after a period of ill-health there is often an abrupt onset of confusion and depression, with disagreeable delusions of persecution and hallucinations. With the subsidence of the acute symptoms the fundamental defect becomes apparent with the symptoms mentioned above—the most prominent being bizarre conduct, incoherent thought and vivid auditory hallucinations.

Catatonia tends, after a depressive phase, to manifest itself by a state of stupor or excitement, which irregularly alternate. In the former we see constrained, fixed attitudes with much muscular tension, and any attempt to move the patient is met with marked resistance (negativism). A state like that of catalepsy is often maintained with curious grimaces and mutism. There may be shown the opposite condition of negativism, *i.e.*, a great suggestibility in which all commands are mechanically obeyed. In the excited phase there is a manic-like condition, with much talking, shouting and general physical activity. The actions are, however, absurd, stereotyped and tend to be oft repeated. Violent impulses are given way to, and much violence is frequently manifested, which may involve homicide and suicide. Delusions and hallucinations are in evidence, and the excited period may quickly abate.

The *paranoid form* often appears somewhat later in life than the others, and is specially differentiated by the presence of somewhat systematized delusions of persecution and grandeur, which are usually absurd and fantastic, with hallucinations of hearing.

In the large majority of cases dementia praecox is a serious, chronic condition, which leads to a progressive dementia. Yet it must not be considered hopeless, for some sufferers seem to recover entirely and others may reach a stage of betterment which permits of some adjustment to life outside a mental hospital. To prognosticate the future in any individual is a very difficult problem. The paranoid form has the worst outlook.

Paranoia.—In its true form this is uncommon, and has been regarded as, perhaps, more a morbid unfolding of a peculiar personality than an actual disease. Exaggerated suspicion and conceit seem to be its emotional groundwork. According to Kraepelin it is characterized by "the furtive development, resulting from inner causes, of a lasting, immovable, delusional system that is accompanied by the complete retention of clearness and order in thinking, willing and acting." It is because of this seeming intellectual soundness that the condition may escape recognition, and few such cases find their way into mental hospitals. Early in life a paranoiac character may evince itself and the individual tends to be quiet, reserved, self-conscious and lacking in confidence, though at the same time ambitious, selfish, proud, with unusual intelligence. There is an increasing tendency to find fault with the environment, and irritability and aggressiveness show themselves. Later disappointments lead to suspicion and blame

on others being engendered until definite delusions of a persecuting nature appear. Such delusions become systematized until the person is convinced that certain people or bodies of people are plotting his downfall. The delusions, however, appear to be logical to a large extent, and not contradictory, though in time a normal person will recognize the weakness of their premises and the exaggerated absurdity of the inferred deductions. Apart from the delusions the paranoiac is apparently sound in his train of ideas, hence the old term "monomania." According to the form of the delusion paranoiacs are commonly described in four types. The persecutory is the commonest; the grandiose have delusions of self-importance and may regard themselves of royal lineage; the erotic, who believe they are beloved and desired in marriage by some unattainable individual; and the querulous, who think themselves delusionally the victims of injustice, and who consequently are appealing to law tribunals for redress of their wrongs. True paranoia is looked upon as incurable.

Paranoid symptoms and paranoid states, akin in some respects to paranoia, may be met with as part of the clinical picture in many types of insanity, such as dementia praecox, general paresis, toxic insanities and manic-depressive insanity.

Imbecility and Idiocy.—These are the severer forms of feeble-mindedness which arise from some developmental defect before birth as a result of injury, or after birth through injury or disease. The feeble-minded are defined as "persons in whose case there exists before birth, or from an early age, mental defectiveness not amounting to imbecility, yet so pronounced that they require care, supervision and control for their own protection or for the protection of others." Their mental defect is slight, and capable of much improvement by educational methods. Ultimately they may be able to take a place in the world, and under favourable circumstances be self-supporting. An *imbecile* can be materially improved by training, but not sufficiently to take a place in the world. The intelligence does not exceed that of a normal child of about seven years.

Idiocy is a state of profound mental defectiveness. The lower grades are unteachable, while the higher may be educated slightly in such ways as attending to the calls of nature. The mental development does not exceed that of a normal child of two years. Physical deformities of various kinds are common, the minor defects being usually referred to as "the stigmata of degeneration." The causes of their failure in development are varied. Heredity has an influence, while accidents and injuries connected with pregnancy and child-birth are common causes. Acute infection and especially syphilis involving the brain, often contribute. General diseases of the mother and her pelvic organs may, under certain conditions, bring about brain malformation. There are several well recognized types:

1. *Amaurotic family idiocy* occurs mainly, if not entirely, in the Jewish race. There is blindness, from atrophy of the optic nerve, and the idiocy is accompanied by paralysis of all four limbs. The child invariably dies before the age of two years.

2. *Cretinism*, due to an inborn deficiency in secretion from the thyroid gland. The effect of treatment with thyroid gland produces marvellous results.

3. *Mongolism*, so called because of the resemblance of the physical characteristics to those belonging to the Mongolian race. Certain features connected with the skull, tongue and eyes are diagnostic.

4. *Hydrocephalus*, commonly known as "water on the brain." The brain is unduly pressed upon and impaired by the excessive quantity of cerebro-spinal fluid which accumulates within the ventricles.

5. *Microcephaly*. The skull is abnormally small, being less than 17 in. in circumference.

6. *Sensory-deprivation Types*. Here there is no structural defect of the brain, but owing to the child being deprived of two or more of the principal senses, such as sight and hearing, upon which mental development depends, a state of severe mental defect is established. Special training, however, and the utilization of other sensory organs, may have excellent results.

7. Other types are known as inflammatory (due to brain in-

flamiation); paralytic (associated with paralysis); epileptic (associated with epilepsy). (See FEEBLE-MINDEDNESS.)

Senile Forms of Insanity.—These may appear after 60 years of age. Accompanying physical decay there may only be a general mental deterioration or dementia, which is characterized by general reduction in intellectual capacities, memory defect, involving recent events, a narrowing of interests, more or less irritability, suspiciousness and restlessness, especially at night. Upon this background of senile dementia various insane symptoms may be ingrafted. There may be a certain amount of confusion, which may be very marked, and memory defects may be associated with all sorts of fabrications (presbyophrenia). Specially depressed or agitated types may be in evidence, and a paranoid condition with delusions of persecution and hallucinations of hearing are at times met with. The abnormal state may be complicated by physical symptoms due to senile morbid brain changes. The course of senile dementia is progressive until death. Such patients finally become completely demented in every respect. After death the brain shows signs of atrophy and there are definite organic changes in its substance, membranes and blood vessels.

Toxic Insanity.—A type due to poisonous substances formed within the body or introduced from without. The former are known as endogenous and the latter exogenous. Many of these are short-lived and therefore do not necessitate commitment to a mental hospital. The amount of a toxin which can be tolerated without inducing insanity is an index of the nervous and mental stability of an individual. The endogenous mainly arise from such infective conditions as influenza, pneumonia, malaria, smallpox, rheumatic or typhoid fever. Though the toxic substances differ in nature, they may result in exactly similar symptoms or, on the other hand, the same poison may excite an outbreak of different forms of insanity depending upon the special morbid potentialities of the personality attacked. Mental symptoms are mainly noted during the febrile period, and a delirious state is the commonest condition. There is first confusion, and this is followed by disorientation for time and place, with restlessness, anxiety and hallucinations of sight and hearing. Excitement may be intense and resemble mania. Speech tends to become incoherent, and drowsiness may give way later to a stuporose state. When the fever is over there is frequently a severe depression, in which suicide has to be thought of. It is at this period, too, that symptoms of manic-depressive insanity or dementia praecox may supervene in an individual so predisposed. The great majority of toxic cases completely recover but a certain number may suffer a lasting mental impairment. A similar state of insanity may be brought about, though rarely, by exhaustion, occurring from haemorrhage, starvation, or excessive physical or mental overwork. In some cases the factors of exhaustion and infection are causative together.

The commonest exogenous toxin productive of insanity is alcohol. As was indicated when the general causes of insanity were being considered, the relation of alcohol to insanity has hitherto been viewed in a much too superficial light. Alcohol, patently, can bring about acute and chronic insanity through its toxic effect, but there are several forms which the more modern psychiatrists look upon as other forms of mental disease, merely coloured by the added factor of alcoholism, or which may be viewed as psychopathic reactions which alcohol has allowed to come to the surface. Though these types of so-called alcoholic insanity will be mentioned here, under their several headings, it will be pointed out that, strictly speaking, they should come under a different classification. Alcohol is, undoubtedly, in its effects an indication of the nervous and mental stability of an individual. *In vino veritas* is a very true maxim, for it is when the influence of wine is at work that the true personality is manifested. The veneer of conscious control is removed, and those who, through head injury or disease, have already a diminution of cerebral control, will the more easily react to its effects. The defect in inhibitions which are so liable to accompany the incidence of certain forms of insanity may easily lead to alcoholic habits, these then being mistaken as causative of the disorder.

Ordinary drunkenness may be pathological, and render unstable

people temporarily insane. Under the influence of variable quantities of alcohol an individual may evince maniacal frenzy, delusions and hallucinations, and may indulge in such anti-social conduct that the law has to step in to restrain him. Subsequent to such attacks there is usually a complete blank in the memory of such episodes. The only true toxic types of alcoholic insanity are delirium tremens, alcoholic dementia and a peculiar form known as Korsakow's psychosis.

Delirium Tremens. This condition of temporary insanity is too short-lived to be seen within the walls of mental hospitals, though abnormal states may follow which necessitate supervision and control. It usually originates in a chronic alcoholic, after a severe drunken bout, but may also occur in an alcoholic who is the victim of acute disease or some gross injury. That sudden abstinence is provocative, as has been thought, is exceedingly doubtful. Most commonly, before the special symptoms manifest themselves, there is a period of a few days in which the sufferer is nervous, sleepless, restless, shaky and has no appetite. The delirium more or less suddenly appears. The patient is quite confused as to time and place and has the most vivid hallucinations, which are predominantly visual. These characteristically take on the form of small animals, such as rats, snakes and insects, but they may be of larger type in all kinds of fantastic shapes. Auditory hallucinations causing apprehension are sometimes present, and all sorts of delusional experiences may be passed through. The emotion is that of great fear of meeting some awful fate and conduct is not only extremely restless, but is apt to show impulsive offence and defence. The delirium may be occupational in character, and the patient is constantly busy carrying out his usual duties in a make-believe world. Speech is incoherent, and mostly in touch with his hallucinatory experiences. Tremor is well-marked, and is mostly noted in the small muscles of the hand, tongue and face. The condition lasts only a few days and terminates in a long sleep. Some, however, die from exhaustion.

Alcoholic dementia is liable to result from the chronic toxic effect of long years of excessive alcoholic indulgence. Insidiously there is a progressive enfeeblement of the intellect, a blunting of judgment, memory, control and morality. Untruthfulness is prominent, and attitudes of jealousy and a feeling of persecution, which are common, are apt to develop into definite delusions. Finally the mental deterioration is extreme, and attended by organic disorders resulting from alcohol. In some cases both the mental and physical signs resemble those seen in general paralysis of the insane.

The third form of a true alcoholic insanity is called after the psychiatrist who first described the condition, and known as *Korsakow's psychosis*. Though the commonest causative toxin is alcohol, other poisons are sometimes responsible. It is comparatively rarely seen before the age of 50, and is noted more in the female sex. It may result immediately from an attack of delirium tremens and has been looked upon as a chronic alcoholic delirium. The characteristic symptom is a peculiar falsification of memory. There is a marked defect in the recording of the events of the present and past for a variable period, but long distant experiences are well recollected. The memory gaps are unconsciously compensated for by being filled by all sorts of fabrications, which are recounted in great detail and have every appearance of truth. The converse seems clear and intelligent, though it is highly confused as to time and place. Hallucinations both of sight and hearing are usually present. The mood is mostly happy and the patient has no insight into his condition. In the physical sphere there is neuritis of many of the peripheral nerves, with perhaps some local paralysis. Besides, various other structures of the nervous system may be involved. As a rule the outlook is not good, and even where much betterment ensues, the memory is left defective.

There are two other forms of insanity which are usually classed as alcoholic in origin, but since the symptoms are not really due to its toxic effect, but to the fact that the alcohol has released morbid potentialities, they should not scientifically be brought under such a heading. There are so-called alcoholic hallucinosis and alcoholic paranoia.

In *alcoholic hallucinosis* the symptoms mainly in evidence are

auditory hallucinations of an unpleasant nature, with delusions of persecution, in which the sexual element tends to be predominant. The patient hears voices accusing him of all sorts of immoral practices, and concerning these he is glibed at and threatened. He is naturally anxious, depressed and apprehensive of harm. The fact that he may identify those around him as his persecutors is liable to render him dangerous and homicidal. On the other hand, suicide as a refuge may be attempted. As a rule, recovery to sanity comes about, but the condition may become chronic.

In *alcoholic paranoia* there is a paranoid state in which hallucinations, if present, are of secondary importance, the characteristic symptom being delusions of jealousy and marital infidelity. These alcoholic delusions of jealousy tend to fluctuate with the amount of alcohol drunk, and commonly disappear quickly when abstinence is enforced in an institution. Very rarely the insanity becomes chronic. Other toxic agents such as opium, cocaine and miscellaneous intoxicants may cause insanity, but are too uncommon and unimportant to need mention.

General Paralysis of the Insane (general paresis, dementia paralytica). This type may be grouped under forms of insanity due to infection, or to those associated with organic brain disease. For simplicity's sake it is spoken of separately. It is due essentially to syphilitic infection of the grey matter of the brain, and the syphilitic virus (*treponema pallidum*) can be microscopically seen there. It is characterized by a progressive and rapid mental deterioration. Five to 15% of the admissions to mental hospitals are of this disease, which affects males much more than females. It develops between the ages of 30 and 50, but there is a juvenile form which may attack the young who are the victims of congenital syphilis. The disorder has a long incubation period and does not show itself usually until 10 or 15 years after infection. The onset is commonly insidious, and manifests itself in a change of character. Former ideals and standards of living are replaced by recklessness, neglect of appearance, gross indulgence, bad moral habits, loss of sense of obligation to family and others. There is a general dulling of comprehension, deficiency of memory, judgment and self-control. There is no insight into these factors, which are often accompanied by a special sense of well-being and ideas of great wealth and power. Sometimes a convulsive attack ushers in the disease. The patient gradually deteriorates mentally and physically and there is an increasing inability to adapt to life. Very bizarre, grandiose delusions are constantly noted but on the other hand there may be depression, with grotesquely absurd delusions consonant with this mood. In the course of time the downhill mental involvement is so profound that the patient may be said to live a purely vegetative existence, and become as helpless as a new-born babe. Atypical cases of course are often met with. Since this form of insanity is due to organic brain disease we must expect definite physical signs to be present, and it is upon these that the diagnosis must be founded. Appearing at some stage of the disease we shall note inequality of the pupils, which react to accommodation but not to light (Argyll-Robertson pupil), changes in tendon reflexes, muscular weakness, tremor, especially of the hands, tongue and face muscles, slurring of speech, and perhaps apoplectic or epileptiform seizures. The blood, when tested, will demonstrate the syphilitic infection (Wasserman reaction) and the cerebrospinal fluid, both chemically and microscopically, will show definite changes. After death the post-mortem findings in the brain are very typical. The outlook is very bad, since a fatal ending as a rule comes about in two to five years. Curious remissions may occur in which for some time the disease process is seemingly stayed or bettered for a varying period, but subsequent to which the patients rapidly go downhill. Of late years new methods of treatment have raised hopes that a cure might be realized, but so far with only indefinite results. The latest consists of the artificial induction of malaria, which in many cases has temporarily brought great improvement. Time will show whether these efforts, combined with anti-syphilitic treatment, brings success. Other forms of insanity may be associated with cerebral syphilis, which are much more amenable to treatment, and consequently have a better prognosis.

Organic Brain Diseases.—Among the organic brain diseases in which insanity not infrequently manifests itself, *arteriosclerosis* is a common condition, and may be intimately connected with senile dementia. Here the changes in the arteries and consequent interference with the cerebral circulation, with some softening of the brain, are productive of the morbid mental symptoms. The patient gradually shows defects in efficiency and memory, with emotional instability and irritability. The mind is apt to get confused at times and delusions of a hypochondriacal, persecutory or jealous nature may appear. The personality is often well-preserved for a prolonged period and insight is good at first, but in time there is a progressive mental deterioration and more or less complete disorganization of the mind ensues. Physically, there will likely be organic nervous signs, with perhaps local paralysis and epileptiform fits. Other organic brain diseases which may be complicated with symptoms of insanity are disseminated sclerosis, locomotor ataxy and epidemic encephalitis.

Epileptic Insanity.—In a certain proportion of cases, if epilepsy begins in early life, it may lead to condition of feeble-mindedness, imbecility or idiocy. In relation with epileptic seizures, or in place of them, various abnormal mental states are liable to arise in some victims, which necessitate their commitment to a mental hospital. In these conditions there may be severe depression, excitement, state of ecstasy or confusion. Epileptic insane patients are apt to be morose, irritable, suspicious and querulous. Any chronic state of insanity will probably be paranoid in nature, with delusions and hallucinations. As a class they are dangerous.

According to the report of the United States Department of Commerce, the number of insane persons in 161 of the 165 State and Federal hospitals for mental disease on Jan. 1, 1927 (exclusive of the State psychopathic hospitals, and the Federal hospitals operated by the Veterans' Bureau, the Public Health Service, the Army and the Navy), was 250,890, as compared with a total of 229,664 in 1923. In the country as a whole the number of mental patients under institutional care shows a steady increase.

HOSPITAL TREATMENT OF INSANITY

The era of real hospitals for the insane may be said to have begun in the 19th century, although there had been established here and there in different parts of the world certain asylums or places of restraint before this period. The prevailing idea of the pathology of insanity in Europe during the middle ages was that of demoniacal possession. The insane were not sick, but possessed of devils, and these devils were only to be exorcised by moral and spiritual agencies. Mediaeval therapeutics in insanity adapted itself to the etiology indicated. Torture and the cruellest forms of punishment were employed. The insane were regarded with abhorrence, and were frequently cast into chains and dungeons.

Until as late as the middle of the 18th century, mildly insane persons were cared for at shrines, or wandered homeless about the country. Such as were deemed a menace to the community were sent to ordinary prisons or chained in dungeons. Thus large numbers of lunatics accumulated in the prisons, and slowly there grew up a sort of distinction between them and criminals, which at length resulted in a separation of the two classes. In time many of the insane were sent to cloisters and monasteries, especially after these began to be abandoned by their former occupants. Thus "Bedlam" (Bethlehem Royal hospital) was originally founded in 1247 as a priory for the brethren and sisters of the Order of the Star of Bethlehem, and was rebuilt as an asylum for the insane in 1676.

Pinel, in 1792, struck the chains from the lunatics huddled in

the Salpêtrière and Bicêtre of Paris, and called upon the world to realize the horrible injustice done to this wretched and suffering class of humanity; but 25 years later, the insane, everywhere in Europe, were still treated brutally, and it was not until 1838 that in France they were all transferred from small houses of detention, workhouses and prisons, to asylums specially constructed for this purpose.

No great advance in the humane and scientific care of the insane was made till towards the middle of the 19th century. Only then did the actual metamorphosis of asylums for detention into hospitals for treatment begin to take place. Hand in hand with this progress there has grown, and still is growing, a tendency to subdivision and specialization of hospitals for this purpose. There are now hospitals for the acutely insane, others for the chronic insane, asylums for the criminal insane, institutions for the feeble-minded and idiots, and colonies for epileptics. There are public institutions for the poor, and well-appointed private retreats and homes for the rich. All these are presided over by properly qualified medical authorities, supervised by unsalaried boards of trustees or managers, and inspected by Government lunacy commissioners, or boards of charities.

It may be said indeed that the modern hospital for the insane does credit to latter-day civilization. Physical restraint is no longer practised. The day of chains—even of wristlets, covered cribs and strait-jackets—is past. Neat dormitories, cosy single rooms, and sitting- and dining-rooms please the eye, and improved methods of treatment are adopted in the way of sleep-producing and alleviating drugs, dietetics, physical culture, hydrotherapy and the like. There are few asylums now without pathological and clinical laboratories.

Germany approaches nearest to an ideal standard of provision for the insane. The highest and best idea which has yet been attained is that of small hospitals for the acutely insane in all cities of more than 50,000 inhabitants, and of colonies for the chronic insane in the rural districts adjacent to centres of population. The best of these colonies are constructed on the principle of a farming hamlet, without barracks, corridor buildings, or pavilions, being similar in most respects to any agricultural community. At the same time all the inhabitants are under medical supervision, and a laboratory for scientific researches forms a highly important part of the equipment. Such a colony is not looked upon indeed as a refuge for the incurable; it is rather a hospital for the sick where treatment is carried on under the most humane and most suitable conditions, and wherein the percentage of recoveries will certainly be larger than in asylums and hospitals as now conducted.

But that the tendency in the direction of the more humane and scientific treatment of the insane is a general and a growing one is manifested in all countries by the steadily increasing abandonment of the former huge cloister-like abodes for the detention of such sufferers.

During the World War the British public insisted that no soldier should be sent to an asylum unless proved to be suffering from an incurable mental disease, or until, after a probation of 12 months, the disease was regarded as incurable; and the success of this method of dealing with mental disease in the army led the board of control to reconsider the question of the early treatment of insanity.

Through the munificence of Dr. Henry Maudsley, the London County Council has built the Maudsley hospital for the study and treatment of mental diseases in the early and curable stage; and here a real effort has been made to deal with insanity on modern rational lines.

It has an out-patients' department, and 150 beds for males and females, together with a qualified staff of medical officers. The Maudsley hospital is a recognized school of the London University, and a course of lectures, together with practical instruction, is given to medical men who are desirous of qualifying for the diploma of psychological medicine. The London County Council give study leave to their medical officers of asylums, and now require officers who apply for senior appointments to possess a university diploma of psychological medicine or a diploma of the

conjoint board of the Royal College of Physicians and Surgeons. Opportunities for research in the pathological laboratory are afforded to suitable applicants by the committee.

The Maudsley hospital, being a rate-aided hospital, is primarily intended for those who have a London settlement, and the charge made varies according to the means of the patient. All inmates of the hospital are voluntary and uncertified. This allays the fear of the patients that they may be made permanent inmates, and inspires them with confidence in their treatment. Out-patients are thereby encouraged to attend the hospital, and in this way a more favourable prognosis is secured, for mental disorders and diseases are thus observed and treated in their incipient stages.

In most London general hospitals special out-patient departments exist for mental diseases, and there is an attempt being made to link up the general hospitals and mental institutions. A few actually admit in-patients with mental illnesses of a type considered suitable to be treated in such an environment.

The United States.—Most of the intensive work in treating insanity is naturally done in special hospitals, but more and more is being done in schools and even in the pre-school period, in habit and child guidance clinics, in outpatient departments, in mental hygiene organizations, in private practice, in general hospitals, in nursing homes and sanatoria. There is much demand for a greater variety of provisions in harmony with the needs of a great variety of patients. The theory and practice of psychiatry (*q.v.*) to-day include all conditions in the treatment of which familiarity with personality development and personality problems and with disorders and diseases of personality is required.

For the treatment of mental disorders the United States show a wide range of unusually inadequate and many unusually modern provisions. In some regions the gaol is still an intermediary station between home and State hospital (some State laws making the sheriff and juries and the gaol the agency for first aid). In only a few States, as in New York, the health officer has to provide intermediate help pending admission to the State institution. As intermediary stations, there are creditable reception hospitals in a number of cities.

As the ideal for treatment there should be reception and treatment hospitals not too far from the homes, either detached or as special divisions in general community hospitals, with country annexes and colonies for cases that would do better outside of cities, and various types of colony provisions for protracted care. A most important task will always be the service in the community, outside of institutions—the "extra-mural psychiatry."

Unfortunately, to maintain adequate hospitals and hospital organization in small as well as in large communities appears to call for too great an expenditure for disorders which the general medical profession and the public—up to but a few decades ago and in many places up to the present—have largely left to charity and moral advice and exhortation and to the "asylums" now called hospitals.

The first really reasonably well supported hospitals in the United States for mental cases were a few private institutions (New York hospital, Massachusetts General, Pennsylvania and similar hospitals) or special foundations (the Hartford Retreat, Butler hospital, Sheppard and Enoch Pratt hospital). For the rank and file, increasingly well-conducted State institutions and State care acts have helped to replace the makeshifts provided by the counties and certain townships, by no means wholly supplanted. Much care should be taken lest the dependence on private philanthropy might have a retarding effect on the education of the tax-paying public.

Psychiatric institutes, clinics and training schools, research centres and especially the National Committee for Mental Hygiene, are doing valiant work for progress. Better training of the

average physician, education of the public by child guidance clinics and community service and examples of organization of local and State work are marking the present trend in many States and in Canada.

May, *Mental Diseases, a public health problem* (1922), and reports of the various State departments which have the State institutions under their care.

INSANITY IN LAW. It would be difficult to find a more satisfactory term for unsoundness of mind than the old phrase hallowed by usage *non compos mentis* and it is interesting to note in the legislation of Saskatchewan the phrases *mentally incompetent person* and *mentally incompetent for lunatic and insane* (No. 65 of 1921). Serving a less useful purpose perhaps are various euphemisms whereby *lunacy*, *insanity*, *lunatic* and *lunatic asylum* are called *mental disorder* or *defect*, *patient* and *mental hospital* respectively (South Africa, no. 38 of 1916). It is to be noted that even countries under the civil law (*i.e.*, countries whose law is rather code law than case law) shrink from definitions of insanity and prefer as we have done to judge of the alleged unsoundness of mind with regard to the circumstances of any particular case. One distinction, however, is practically universal, *viz.*, between *idiot* and *lunatic*; idiocy is considered to be natural and lunacy acquired. The Idiots Act of 1836 has, however, been repealed by the Mental Deficiency Acts of 1913 and 1927 and certain definitions attempted. The latter acts introduce the new terms *mental defective* and *defective*. For all legal purposes these can be dealt with under the act of 1890 as persons of unsound mind. The Mental Deficiency Acts provide for the segregation of persons if *defective*, with a separate code for their benefit. (See MENTAL DEFICIENCY.)

When a man becomes unable to manage himself or his affairs, society, to protect herself and the lunatic, changes his status by taking the management of his person or of his property, or of both, out of his hands. But, since rights and obligations are co-relative, the civil incapacity resulting from the changed status carries with it a certain freedom from responsibility which forms the subject matter of the substantive law of lunacy. Of these the most dramatic is the criminal irresponsibility of the insane. Other examples of irresponsibility are the avoiding of certain contracts, including, under certain circumstances, marriage and the setting aside of wills.

No person of unsound mind can, in Great-Britain, be detained, nor can the management of his property pass into the hands of another, except by due process of law, and we shall consider how this is done and what safeguards besides the writ of habeas corpus (*q.v.*) there are against improper detention.

The adjective law of insanity is codified in the Lunacy Acts, 1890-1922. In the middle ages the wardship of idiots and lunatics was in the king, who under the Statute De Prerogativa Regis enjoyed an idiot's property, subject to the obligation to provide him with necessities, but was a strict trustee for a lunatic. Idiots and lunatics were so found on inquisitions under the writs *De Idiota Inquirendo* and *De Lunatico Inquirendo*; but as juries avoided finding a verdict of idiocy the former writ fell into desuetude. The latter, however, exists to this day and is described in part 3 of the Lunacy Act of 1890. Certain important legal distinctions exist between the status of a "lunatic so found" (*i.e.*, under the inquisition) and a "lunatic not so found"; the latter term meaning a person whose unsoundness of mind has been legally established by another procedure than inquisition as, *e.g.*, by certification.

On an inquisition the issue is whether the person is of unsound mind so as to be incapable of managing himself or his affairs. (1) A lunatic so found is looked after by a committee. The committee of the person and the committee of the property are not necessarily one and the same person (L.A. 1890, pt. 4). In some cases a lunatic so found is allowed his liberty but not the management of his property (L.A. 1890, s. 98 [2]). The contracts entered into by a lunatic so found are void *ab initio* as also is marriage

even during a lucid interval. He may, however, make a valid will during a lucid interval, and even at other times his will is valid if it appears that he was of a "disposing mind." (2) The person and property of lunatics not so found are governed by other rules. The property of the average lunatic is so soon swallowed up in the arrangements for his care that it is not his property that interests the State, but the absence of it. (See POOR LAW.) A lunatic may be detained in any one of seven ways: (1) On an urgency order signed by a relative or other interested person and accompanied by one medical certificate. The judicial authority does not intervene in this order, which lasts only seven days. (2) On a petition by relatives; two medical certificates (L.A. 1890, s. 4); the usual procedure. (3) On the information of a constable, etc., that a lunatic, not a pauper, is not under proper care and control or is cruelly treated or neglected by any relative, etc.; two medical certificates (s. 13). (4) On the information of a constable, etc., that any person, whether pauper or not, is "wandering at large" and deemed to be a lunatic; one medical certificate. (5) Under s. 23 two commissioners in lunacy may, with one medical certificate, send a pauper lunatic or alleged lunatic to an asylum. (6) On the information of a parish officer, with one medical certificate, pauper lunatics may be dealt with (s. 14). Methods 2 and 3 require the intervention of the judicial authority defined in ss. 9 and 10. The judicial authority may act in cases 4 and 6, but a justice of the peace will suffice. (7) The committee of the person or a master in lunacy may, of course, without medical certificates, sign a reception order after a lunatic has been formally so found and a committee of the person may sign in case 1.

Elaborate safeguards against improper detention are provided by the Lunacy Act, 1890. The powers and duties of the commissioners in lunacy are transferred by the Mental Deficiency Act, 1913, to a board of control. Two or more commissioners, one of whom must be a doctor and one a barrister, must visit every asylum at least once a year. In addition, two members at least of the visiting committee appointed by the local authority must inspect every two months every part of an asylum and see every patient therein, so that they may have an opportunity of making complaints. There are also provisions for visiting hospitals, licensed houses and single patients. Lunatics so found are visited by "chancery visitors."

The Royal Commission on Lunacy, 1926, was unable to find (p. 39) that any of the alleged cases of improper detention could be supported on the evidence. This royal commission was appointed in 1924 to enquire, as regards England and Wales, into the law and procedure relating to the certification, detention and care of persons of unsound mind; and to consider to what extent provision should be made for the treatment of such persons without certification.

The report considers that "insanity is after all only a disease like other diseases" and complains that "the keynote in the past has been detention; the keynote in the future ought to be treatment and prevention." Whatever may be thought of the first proposition, in favour of which it is doubtful whether any considerable body of medical opinion exists, it may be pointed out with regard to the second that the idea of treatment of insanity is no new one. A medical certificate under the Lunacy Acts contains the phrase "and is a proper person to be taken charge of and detained under care and treatment." This conception is 100 years old and dates back to an act of 1828 to regulate the care and treatment of insane persons in England, repealing various acts for regulating madhouses. (Nor is the idea of treatment a new one on the Continent, see the French Lunacy Act of 1838—*Loi sur les Aliénés*—Art. 1.)

The royal commission recommended the removal of the "stigma of pauperization" by "divorcing lunacy law and administration from the poor law" and the avoidance of the "stigma of certification" by the putting of certain cases under care and treatment without full certification. This seems to throw much more responsibility on the medical man, who already, if he attempts to treat a borderline case himself, may be prosecuted under s. 315 (1) of the act for receiving an alleged lunatic without an order; or

if he certifies such a case he may later be sued by a patient who considers himself to have been wrongfully certified. An excellent summary and criticism of the present state of the law as to the responsibility of medical men is found in Mr. Justice McCardie's judgment in case of *de Freville v. Dill*, [(1927) 43 T. L. R. 702].

In actions at common law the issue is: Was the alleged lunatic at the date in question capable of understanding the nature of the act he was performing. The contract of a lunatic not so found is voidable but not void *ab initio* (contrast case of a lunatic so found) and it must be shown that the other was aware of the lunatic's condition. A lunatic not so found may therefore make a valid contract in a lucid interval, nor need he have fully recovered (*ex parte* Hoyland [1805] 11 Ves. 10).

Marriage (*q.v.*) is more than a contract involving, as it does, a change of status. By the Marriage of Lunatics Act, 1811, the "marriage" of a lunatic so found, even during a lucid interval, is void. The marriage of a lunatic not so found is voidable if insanity of a pronounced type can be shown to have existed at the time of the ceremony.

In probate actions (actions on wills) the issue is: was the testator of a sound and disposing mind. In particular he must be able to recall the several persons who may be fitting objects of his bounty and understand the relation of the various beneficiaries to himself and their respective claims upon his bounty. A medical man who attests a will *ipso facto* certifies that, in his opinion, the testator is of a sound disposing mind as regards that particular will.

In the criminal law the question for the jury, if insanity is pleaded, is: Was the person at the time of committing the act labouring from such a defect of reason, from disease of the mind, as not to know the quality of the act he was doing; or, if he did know it, did he know that what he was doing was wrong. This issue is a summary of the famous M'Naughten rules. In 1843 one M'Naughten, under the delusion that he was being persecuted by Sir Robert Peel, killed that statesman's secretary. Insanity was pleaded on the ground that the delusion deprived the prisoner of any control over acts connected with the delusion, and the prisoner was found not guilty on the ground of insanity. The case gave rise to a good deal of discussion and led to the unusual step of putting a hypothetical case to the law lords; unusual, because in English law judges give judgment after hearing the argument in an actual case. The answers of the judges on this occasion are called the M'Naughten rules. Not having been decided in an actual trial, they are technically not authority, but in practice their authority is great.

Writing in *The Law Relating to Lunacy*, Theobald says (1924 at p. 242) "The more recent charges given by the judges in trials for murder shows that, though the rules in M'Naughten's case are relied on, yet being abstract and general in their terms the judges are careful to adapt and apply them to the circumstances of each case."

In July 1922 the then lord chancellor (Lord Birkenhead) appointed a committee to consider what changes, if any, were desirable in the existing law practice and procedure relating to criminal trials in which the plea of insanity as a defence is raised, and whether any, and if so what, changes shall be made in the existing law and practice in respect of cases falling within the provisions of s. 2(4) of the Criminal Lunatics Act, 1884. The committee's recommendation (1. 11. 1923), among others, that a modified recognition should be given to the doctrine of irresistible impulse was referred to 12 high court judges in 1924; ten advised against it.

Insanity is seldom pleaded except in murder trials, but it must be remembered (as pointed out by Lord Birkenhead, *Times*, 26. v. 1924) that any alteration in the law will be far-reaching and affect all crimes. All that we are entitled to say about an irresistible impulse is that in fact it has not been resisted. (F. T. G.)

BIBLIOGRAPHY.—See N. A. Heywood and A. S. Massey, *Lunacy Practice* (1st ed., 1900, 5th ed., 1920); C. A. Mercier, *A Text-book of Insanity* (1902; 2nd ed. rewritten, 1914); H. S. Theobald, *The Law relating to Lunacy* (1924).

United States.—In America the law does not follow either

medicine or metaphysics in its conception or definition of insanity. The whole American system of criminal law postulates moral responsibility, and persistently refuses to accept any other standard. Hence, the law will not entangle itself in the ancient controversy between metaphysicians as to the freedom of the will. For the purpose of accountability for crime, it holds that the deliberate acts of sound minds involve discrimination and are not necessitated. So, likewise, it holds that such accountability is not nullified by mere mental or psychiatric derangement, however extreme in itself. Hence, while medical knowledge may be necessary rightly to apply the law's definition of insanity, the prevailing legal definition has an ethical and not a medical or psychological content.

This prevailing definition, though variously worded by different courts and legislatures, is, in essence, that given in Sect. 1,120 of the Penal Law of the State of New York, to wit that:—

A person is not excused from criminal liability as an idiot, imbecile, lunatic, or insane person, except upon proof that, at the time of committing the alleged criminal act, he was laboring under such a defect of reason as not to know the nature and quality of the act he was doing, or not to know that the act was wrong.

This statutory definition is taken, almost verbatim, from the answer of the 15 judges of England to the questions propounded to them by the House of Lords in 1843 in M'Naughten's case (10 Cl. and F. 200). It draws no distinction, in point of criminal responsibility, between insanity or idiocy or imbecility; and it measures such responsibility by the deprivation of understanding as to the particular act rather than in general. Under this definition, knowledge of the nature and quality of the act has reference to its physical nature and quality, and knowledge that the act is wrong refers to its moral, rather than its legal side, although knowledge of its illegality may *imply* knowledge of its immorality, since obedience to the law is a moral duty. Hence, where an insane delusion produces a conflict between moral duty and a known man-made law, the defence of insanity is still available. (*People v. Schmidt*, 216 N. Y. 324, 338.)

Implicit in this definition of legal insanity, is the subsidiary principle declared by many American courts that a sufferer from insane delusions must be judged as to his knowledge of the nature, quality and morality of his act by the supposed facts presented by the delusion.

In a few States the legal definition of insanity has been so enlarged as to include irresistible impulse. This test assumes that, even though there may be full realization of the nature, quality and immorality of the act, nevertheless, through mental or psychic disease the defendant may have lost all power to refrain, and hence can be held to no legal responsibility. But this additional definition is rejected in most States as involving the law too deeply in metaphysics and as not affording a safe basis of legal adjudication. Hence, capacity to distinguish between right and wrong, without power of choosing between them, is not recognized, except in the law of a very few States. According to the great weight of authority, where the accused relies on insanity, he has the burden of proof upon that issue. A person while insane cannot be required to plead or to undergo trial or sentence. The manner of determining insanity at the time of the offence or at the time of trial or sentence is usually regulated by statutes which differ widely as between the various States.

Throughout the United States there is a growing tendency to test the issue of insanity in advance of trial and by more scientific means than a battle of hired experts. There is also a growing appreciation of the fact that habitual criminality may in itself be a symptom of mental derangement. Both these new trends of thought manifested themselves in a statute (ch. 415) passed by the State of Massachusetts in 1921 which provided that an indicted person, accused of or known to have been previously convicted of a felony or previously indicted more than once, shall be examined by the State department of mental diseases as to any mental condition or defect which would affect his criminal responsibility. The official report is accessible to the court and to both sides, and is admissible as evidence, although not conclusive. If the prisoner is found insane he is committed immediately to a State hospital. This law has almost completely

eliminated in Massachusetts the trial of a plea of insanity and the familiar duel of hired experts. Under it, accused persons mentally irresponsible are speedily placed in hospitals and treated medically rather than punitively.

In civil matters, the law is relieved of the question of guilty responsibility, and hence adopts various definitions of insanity, depending upon the nature of the acts involved. A person medically insane may, nevertheless, legally make a contract, or appoint an agent, or convey property, if he is able to comprehend, in a reasonable manner, the nature and effect of his act. He may make a will if he has sufficient mind and memory reasonably to understand the nature of the business in which he is engaged, to comprehend the character and extent of his estate, and to recollect the natural objects of his bounty. An insane person is liable for his tortious acts or negligence, except where actual intent is an essential element of the wrong, as, for example, in the case of such defamation as is actionable only when uttered with conscious malice.

Glueck, *Mental Disorder and the Criminal Law* (with appendix of state legislation and interpretative decisions, 1925); J. Koren, *Summaries of Laws Relating to the Commitment and Care of the Insane in the United States* (1912).

INSCRIPTIONS, documents incised on some hard or permanent material in the form of letters or other conventional signs, for the purpose of conveying some information or preserving a record. They are, therefore, to be distinguished on the one hand from manuscripts, or documents written on papyrus, parchment, paper or other more or less smooth surfaces, by means of a brush, reed or pen and some coloured fluid (see **PALAEOGRAPHY** and **PAPYROLOGY**); and on the other hand from pictures or reliefs intended to convey information or to record events (see **PICTOGRAPHY**), though inscriptions were often combined with such pictures or reliefs, especially in primitive times. There are also some classes of documents which are intermediate between inscriptions and manuscripts, such as writing incised with a stylus or sharp pointed instrument upon tablets covered with a thin coating of wax, or scratched upon pottery or other hard materials (*ostraka*). But as the forms of the letters and the character of the writing in both these cases approximate to what is found in manuscripts, they are usually considered to belong to that class of document; but *graffiti*, or casual scratching on walls, rocks or fragments of pottery, are sometimes included in the study of inscriptions, because they often fill gaps in our knowledge, and, in early times at least, do not differ in form or character from ordinary inscriptions. A good example is offered by the names and other records scratched by Greek mercenaries at the time of Psammetichus on the legs of the colossal statues at Abu Simbel in Egypt. As one of the earliest examples of the use of the Greek alphabet, these find their place in the history of inscriptions. Where, on the other hand, we find casual notes, as well as receipts, accounts, etc., scratched upon potsherds or *ostraka*, we realize that these are merely a cheap substitute for more expensive material such as papyrus, and that the study of such *ostraka* cannot be separated from that of manuscripts on papyrus, and really forms a branch of palaeography rather than of epigraphy.

A. FORM

1. **Materials and Technique.**—*Materials.* Inscriptions were commonly incised on stone or marble, on metal, or on wood (though this last material has hardly ever survived, except in Egypt), or on terra-cotta. In Egypt and Mesopotamia hard stones were frequently used for the purpose, and the inscriptions are therefore well preserved and easy to read. In Greece the favourite material, especially in Athens, was white marble, which takes an admirably clear lettering, but is liable to weathering of the surface if exposed, and to wear if rebuilt into pavements or similar structures. Many other kinds of stone, both hard and soft, were often used, especially crystalline limestones, which do not easily take a smooth surface, and which, therefore, are often difficult to decipher, owing to accidental marks or roughness of the material.

The metal most commonly used for inscriptions was bronze;

flat tablets of this were often made for affixing to the walls of temples and other buildings. Occasionally such tablets were made of silver or gold; and inscriptions were often incised on vessels made of any of these metals. Inscriptions on metal were nearly always incised, not cast. An important class of inscriptions are the legends on coins; these were struck from the die. (See **NUMISMATICS**.) Clay was very extensively used for inscriptions in Mesopotamia and in Crete. In this case the symbols were incised or impressed on specially prepared tablets when the clay was soft, and it was subsequently hardened by fire. In Greece, many inscriptions on vases were painted before firing, in that case often having reference to the scenes represented, or incised after firing; potsherds (*ostraka*) were often used as a cheap writing material. Inscriptions were also often impressed from a mould upon wet clay before firing, in the case of tiles, amphora handles, etc., and in these cases often supply valuable information as to the buildings to which they belong or the place from which they took their origin.

The *tools* used for making inscriptions varied with the material; most of them were some kind of chisel, usually with a square blade; early inscriptions were sometimes made on hard rock by successive blows with a punch or pointed hammer. Sometimes a circular punch was used for O or a letter of which O formed a part.

Styles of Cutting. Early inscriptions, which are often amateur work, are frequently very irregular in their cutting. But in almost all examples of later work, the inscriptions are evidently cut by professionals, and there are definite styles and methods belonging to various places and periods. In Egypt, for instance, the hieroglyphs (*q.v.*) are carefully and delicately cut in early times, and in later periods become more careless and conventional. In Greece, the best work was done in the 5th and 4th centuries B.C. in Athens; the letters were all exact and regular in shape, with no adventitious ornaments, and were, especially in the 5th century, usually exactly aligned with the letters above and below, as well as those on each side. The result is a beauty and simplicity of effect that has never been surpassed. At that time all the strokes were made of equal thickness, but in the 4th century B.C. and later there came in the custom of holding the chisel obliquely to the surface, thus producing a wedge-shaped stroke. A similar custom in Mesopotamia gave rise to the so-called *cuneiform* system (*q.v.*). On metal inscriptions in Greece this same effect appears earlier than on stone or marble. In the 3rd century and later it becomes common to introduce *apices* or ornamental ends to the strokes, a custom which prevails to the present day in our ordinary capital letters. The custom of making different strokes and different parts of curves of varying thickness became common in Roman inscriptions, which developed a monumental style of their own, varying from period to period. Inscriptions can often be approximately dated by the style of the cutting as well as by the shapes of the letters; skill in doing this can only be acquired by a careful and minute study of originals and facsimiles.

Inscriptions vary greatly in size according to the position where they were intended to be read, their purpose, and the skill of the cutter. Some inscriptions are of great length, the longest, a statement of accounts of the temple at Delos, under Athenian administration, being nearly half as long as a book of Thucydides; and many other inscriptions approach this in length.

2. **Symbols and Forms of Writing.**—The origin of *writing* and the evolution of the *alphabet* are discussed in the special articles upon those subjects. For the present purpose it is sufficient to note that most of the forms of writing known to us originated in some system of picture-writing, which developed into a hieroglyphic system. Such systems appear to have originated independently in different parts of the world—in Egypt, Mesopotamia, Crete, among the Hittites and in China and America. The evidence for all of these is mainly to be found in inscriptions. The development from Ideographs (or direct representation of an object or idea) to symbols of phonetic value, and so to syllabaries or alphabets, took place in many different systems to various degrees. But the first people to invent a completely alphabetic system of writing were the Phoenicians, from whom the Greeks bor-

rowed it with certain modifications and improvements. From the Greek was derived the Latin, and from the two all the alphabets of European peoples. It is still a matter of dispute whether the Phoenician was derived from the Egyptian.

The hieroglyphic symbols naturally tended to be conventionalized and simplified for convenience of cutting, in accordance with the materials and tools employed. In many cases they developed from a pictorial to a linear form. It is possible that some of these linear forms may not be derived from hieroglyphs, but from purely conventional geometrical forms, such as were widely used at all periods and places as owners' or masons' marks. The tendency of linear forms to become wedge-shaped is most conspicuous in cuneiform, but as has been noticed, the same tendency occurs in Greek inscriptions of the 3rd and 2nd centuries B.C. and earlier in inscriptions incised on bronze.

In the north of Europe the Ogham (*q.v.*) inscriptions are alphabetic, and are apparently an independent invention on arbitrary lines, like the Morse code; but Runes, which were extensively used in the same region, are derived from the Greek or the Latin alphabets.

In most alphabetic systems there are also found in inscriptions certain symbols which are not strictly alphabetic or phonetic in character. The commonest of these are the various systems of numerals that are used in different times and places. It is impossible here to give any full description of these different systems; but a brief account may be given of the principles underlying them. Most of them are based upon a decimal system, doubtless owing to the habit of counting on the fingers. In some cases the symbols are simple and obvious, as in the Cretan script, where circles (or *rhombi*), dots and lines are used for hundreds, tens and units, each being repeated as often as necessary; and a similar system for the lower denominations is used at Epidaurus in the 4th century B.C. In Athens the usual system was to indicate each denomination by its initial, M for Μύριοι (10,000), X for χίλιοι (1,000), H for ἑκατόν (100), Δ for δέκα (10) π for πέντε (5) and I for units. The other Greek system followed that derived from the Phoenicians, using the letters of the alphabet in their conventional order from one to nine, 10 to 90 and 100 to 900; in this arrangement obsolete letters were retained in their original places so as to give the requisite number of 27 symbols. The Roman system of numerals—M, D, C, L, X, V, I (for 1,000, 500, 100, 50, 10, 5 and 1) is generally supposed to have arisen from the adaptation of those symbols in the Greek alphabet which the Romans did not want; an alternative theory is that it is simplified from a series of ideographs representing the spread hand, the fingers and so on.

Apart from numerals, the use of initials in the place of complete words was not common in early times. It became, however, very frequent in Roman inscriptions, which sometimes are made up almost entirely of such abbreviations and can only be understood by those familiar with the formulae. A list of the commonest of these will be found under ABBREVIATION. Compensia or monograms also occur in later Greek and Roman times, and become very common and very difficult to interpret in early Christian and Byzantine inscriptions.

Some kind of punctuation is often found in inscriptions of all kinds. In Greek inscriptions a vertical line or a dot, or dots, sometimes indicates the separation between sentences or words, but words are seldom separated by spaces as in modern printing, so that the text is continuous and no division of words exists. This is particularly the case with Greek inscriptions of the best period. In Roman inscriptions it was usual to separate the words by dots. In certain inscriptions a cross (+) was used to indicate the beginning of an inscription, especially when its direction was erratic. Christian inscriptions sometimes begin with a cross, which doubtless had a symbolic meaning; and a leaf or other device was often placed at the end.

The direction of the writing varies greatly in different places and times. The letters or symbols may be arranged vertically below one another, and read from top to bottom, or horizontally, either from right to left or left to right; they may also be arranged in a kind of pattern—in which case their order may be

indeterminate, or in a wandering or curved line, or left to right and right to left alternately (*boustrophedon*, or as an ox in ploughing). Most Semitic alphabets, including Phoenician, read from right to left; and the earliest Greek inscriptions follow the same direction. But the direction from left to right became regular in Greece after the 6th century B.C., and consequently is adopted by the Romans and in all European systems. The individual letters or symbols usually face in the same direction as the writing, as a whole.

3. **The Position or Place** of inscriptions depends greatly upon their purpose or intention. When they have a direct relation to the sculptures, reliefs or paintings with which they are associated, they often form a kind of pattern to fill the background or vacant spaces between the figures; but sometimes, especially in Mesopotamian statues or reliefs, they are cut right across the figures without any regard to the artistic effect. In late Greek or Roman work it is usual to cut any inscription relative to a statue or relief upon the basis on which this is mounted; but short inscriptions such as dedications or artists' signatures are often placed in some inconspicuous position upon the work itself. In the case of painted vases, the inscriptions relative to the subject represented are usually painted; but dedications and other inscriptions are often incised after the vase has been fired.

In Egypt, inscriptions were often inscribed or painted upon the inner walls of tombs, whether they referred to religious belief or ritual, or to the honours and possessions of the deceased; they were intended for his benefit and convenience rather than for the information of others, so as to perpetuate his familiar surroundings, not to make him live in the memory of his successors. The information which we derive from such inscriptions is invaluable to us; but such was not the intention with which they were made. On the other hand, inscriptions which were intended to be seen by the public and to perpetuate a record of events, or to supply useful information, were usually placed in places of common resort, above all in temples and sacred precincts. Sometimes they were cut on convenient rock faces, sometimes upon the walls of temples or other buildings. Most frequently the slabs of marble (*stelae*), stone, metal or other material upon which the inscriptions were incised were set up in convenient positions to be read, in any places of public resort. This was the method of publication of all laws, decrees and official notices, of treaties and contracts, of honours to officials or private citizens, of religious dedications and prescriptions of ritual. Inscribed tombstones were set up over graves, which were usually placed along the chief roads leading out of a town, the most familiar example being the sacred way from Athens to Eleusis. Inscriptions commemorative of victories or other great events were only in exceptional cases erected upon the spot; more often such memorials were set up in some great religious centre such as Delphi or Olympia. But boundary stones were necessarily placed on the line which they defined.

Chief Periods and Nationalities.—The study of inscriptions supplies an important contribution to the history of many lands and peoples. In some cases, as in Egypt and Mesopotamia, it forms almost the only source of information in the absence of literary records; in others, as in Greece and Rome, it offers a most valuable supplement and comment to what is otherwise recorded.

Both Egyptian and Mesopotamian inscriptions go back to an extremely early date; it is at present uncertain which is the earlier, but both show, before 3500 B.C. and possibly much earlier, a complete, organized system of writing which implies many centuries of development behind it. The Egyptian hieroglyphic system, as used in inscriptions, continued without any essential change of character until Roman times, though various systems of hieratic modification were used at different times. On the famous Rosetta stone, in the British Museum, which first gave the clue to the interpretation of Egyptian writing, hieroglyphic, hieratic and Greek versions of the same decree are given side by side. Its date is 195 B.C. The Mesopotamian linear symbols developed mainly for technical reasons, into a wedge-shaped or cuneiform system, which was adopted in modified forms and applied to different languages through some thousands of years, Sumerian,

Babylonian, Assyrian and Persian, until it was superseded, after the conquests of Alexander, by Greek. An independent hieroglyphic system, which also developed into various linear scripts, existed in Crete during the Middle and Late Minoan periods, from about 3000, probably, to the fall of Cnossus, about 1500 B.C. The Hittite hieroglyphs correspond to the period of the Hittite empire in North Syria and Asia Minor from about 2000 to 800 B.C.; from it, according to one theory, arose the Cypriote syllabary, which continued in use until the 4th century B.C. or later.

The earliest Phoenician inscriptions known date from about the 10th century B.C., and the alphabet remained in use down to the 3rd century B.C. It was modified and adopted by the Greeks at an uncertain date; the earliest Greek inscriptions are generally dated in the 7th century B.C.

In early times each Greek State had its own alphabet; but in the year 403 B.C. (the archonship of Euclides) the Ionian alphabet, which is the one used now for Greek capital letters, was officially adopted by Athens, and soon became universal in Greece. From the various Greek alphabets the different local Italian alphabets, including the Etruscan, were derived with various modifications. The Roman alphabet was among these, being based on the alphabet of Caere, a Chalcidian colony. There are a few very early Roman inscriptions; but they do not become common until the 3rd century B.C.; from that time the letters took much the same forms as they preserve to the present day.

The custom of putting inscriptions in Greek and in Latin on buildings and other monuments continued through mediæval times, and is still customary, classical forms being frequently imitated. The latest dated inscription in the Greek Corpus records the building of a bridge in Sicily in A.D. 1121. The series of Byzantine inscriptions continues practically without interruption to the present day; and Latin retains its use as a universal language in religious, public and private inscriptions.

Methods of Dating.—It is often possible to date an inscription approximately by the style of the lettering, or even by the alphabet used. Thus at Athens the Ionic alphabet was adopted in place of the early Attic alphabet in the archonship of Euclides, 403 B.C., according to a decree proposed by Archinus. But the change was already in process in private inscriptions, and even in official documents Ionic forms are sometimes found earlier. Inscriptions are dated in various ways, mostly by giving the name of a king, magistrate or priest. In the case of kings, they only give an approximate date, unless the year of his reign is given also. But in the case of most independent cities, the date is given by the name of an annual magistrate, and thus the year is precisely indicated. At Athens, the name used was that of the Eponymous Archon, and as an almost complete list of these has been drawn up from inscriptions and other sources, this means of dating is quite satisfactory. The custom of dating by Olympiads, which is familiar to us from later Greek and Roman writers, was rarely used in early Greece, except in connection with athletic victories. Many inscriptions are dated from various local eras, often based upon historical events, such as the foundation of a town or festival, the organization of a province, or even the visit of an emperor. The number of these eras in later times, especially in Asia Minor, becomes very bewildering. In Attic decrees, and some others, it was also usual to give the day of the month.

In Greek inscriptions of the Roman period the year of the emperor is defined by the number of his consulate, or other indications or titles, as in the corresponding Latin inscriptions. In later times, the dating is commonly by "Indiction"; but as this only gives the number of the year within the 15-year period, but leaves that period undefined, such dating is very inconvenient except for merely temporary use. In the Eastern empire the date from the creation of the world (5509 B.C.) is sometimes given; but the date of the Christian era is hardly ever used.

B. CONTENT

Purpose of Inscriptions.—Inscriptions, as above defined, may be roughly divided into two main classes: those in which the inscription was subservient to the use or purpose of the object

on which it was inscribed, or at any rate had a direct relation to that object—for example, the name of the owner or the record of dedication to a god—and those in which the inscription existed independently for its own sake, or for the sake of the information which it recorded, and the object on which it was inscribed was either made for the purpose, as a slab of marble or plate of bronze, or was made use of, as in the case of a convenient wall or the surface of a rock, or even a potsherd. The walls of buildings are often covered with such inscriptions, especially if they are in a conspicuous or convenient position, and so offer an obvious means of publicity.

For us, accustomed as we are to a vast mass of books, newspapers and other printed documents, it is difficult to realize the extensive use and great convenience assigned to inscriptions in ancient times. Not only were public announcements of all sorts, such as we should make known by advertisements or posters, thus placed before the public, but all kinds of records and enactments—codes of law and political decrees; regulations for all matters, civil and religious; accounts and contracts, public and private; treaties between states; records of public and private benefactions and dedications, and all matters of administration; honours to the living and to the memory of the dead. Many of these were intended to preserve for all time the records which they contained; but others must have been of only temporary interest. It seems, therefore, the more remarkable that they should have been incised on permanent material such as bronze, marble or stone—and incised in the first instance, with a care and perfection of technique which have led to their survival to the present day, so as to preserve for us invaluable evidence as to the life and institutions of the people who made them. Temporary and permanent value are thus often combined in the same inscription. For instance, an Athenian citizen, visiting the Acropolis or the Market Place, could satisfy himself at first hand as to treaties or decrees of the people, public accounts or state income and expenditure. And at the same time these documents preserved for all time much history, both social and political.

Relative Inscriptions.—Inscriptions having a direct relation to the object, or representation, on which they are inscribed, vary greatly in their contents. Those relating to picture or relief chronicles of the victories or exploits of kings, as in Egypt and Mesopotamia, serve as a record of the events, and help to interpret the scenes. Such inscriptions are not common in Greek or Roman work; but frequently, especially in early Greek times, and on vases, the names of persons and even of objects are written beside them for the purpose of identification, and sometimes a speech issues from the mouth of a figure. On the carved wooden chest of Cypselus, of about 600 B.C. hexameter verses were written, curving about among the figures, and giving a description of each scene. The bases of statues and reliefs often had inscriptions cut upon them for identification and record. This was particularly the case with honorary statues and tombstones. In other cases, where there is an evident relation between the artistic representation and the inscription, the figures are subordinate and seem merely to illustrate the text, as when a treaty between Athens and Samos has a relief at its head representing the goddesses Athena and Hera clasping hands, as representatives of their respective cities. In other cases, the arms or device of a city is carved on an inscription, almost like a seal on a document. In all these cases the figures and the inscription are part of a common design, whether carried out by the same hand or not. But in the case of owners' marks or names cut on vases or other objects, or of the dedication of such objects, the inscription is not necessarily contemporary; it may indeed be misleading, as in the case, mentioned with disapproval by Cicero, of using again old Greek statues and placing new dedicatory inscriptions on them in Roman times; for instance, one of the statues of Athenian knights of the 5th century B.C. placed at the entrance of the Acropolis, had a later inscription cut on its base to make it serve as an equestrian statue of Germanicus, probably in 18 A.D. when he visited Athens. In Egypt and Mesopotamia also it is not unusual to find the name of a later king or official cut upon an earlier work.

Independent Inscriptions.—The majority of inscriptions are of independent value and interest, the object on which they are cut being either provided for the purpose or utilized as convenient and suitable. Such inscriptions may be classified as (a) *Religious* and (b) *Political and Social*. The distinction between the two is not always easy to draw; for in almost all ancient civilizations religion was a part of the established service of the State, and was under public control, or at least was closely bound up with political administration. It follows that many inscriptions relating to religious matters take the form of political decrees or state documents, and therefore might, especially as far as form is concerned, be included in either category; but it is usually possible to classify them according to their contents and intention.

GREEK INSCRIPTIONS

(a) **Religious.**—1. *Temples, Their Foundation and Administration.*—A temple was often a kind of religious corporation under the control of the State; and its accounts and details of administration were made public at frequent intervals, usually annually, by means of inscriptions, exhibited to public view in its precinct. Many such inscriptions have been found, and supply a great deal of information that can be obtained from no other source. Some great temples, such as that of Apollo on the island of Delos, held great amounts of property, both real and portable, the latter taking the form either of more or less precious offerings dedicated in the temple and its surrounding buildings, or of coined money. The inscriptions accordingly record gifts and acquisitions of landed property, leases and assignments, payments of rent and fines for default, loans and interest and many other business transactions suitable to a great landed proprietor or to a bank. They therefore throw much light upon the social and economic conditions of ancient life, such as are nowhere else recorded. Again, the lists of offerings dedicated in the temple and other buildings enable us to realize almost visually the appearance of their contents. These are described as being on the floor, on the walls, on shelves or in cases; they consisted of vases and other objects suitable for use in the temple service; ornaments and jewels; statuettes, mostly in gold and silver; weapons and tools; coined money; and bullion, mostly melted down from old offerings. The detailed care that was taken in this last case, to ensure that the full weight of these objects was preserved, whether made into a new vessel or not, is recorded in other inscriptions. These elaborate inventories were checked and revised by each successive board of administrators, and gave the best possible security against any robbery or peculation. In addition to such general lists, there are also innumerable records of various gifts and acquisitions, whether of land and houses, or of movable property of all sorts. Buildings and repairs are also recorded, sometimes by the State, sometimes by individuals, whose piety and generosity are suitably honoured. In form, these are often hardly to be distinguished from public works of a secular character, which must be mentioned later.

The inscriptions on or belonging to special dedications are often of great historical interest—there need only be quoted the inscription on the famous snake column, once at Delphi and now in the Hippodrome at Constantinople, with the list of the Greek States which took part in the Persian war; and that relating to the Roman arms dedicated by Pyrrhus of Epirus at Dodona after his victories. Most of the great temples being of immemorial sanctity, it is hardly to be expected that any records of their foundation should be found in inscriptions. But on the other hand we have many accounts of the dedication of new temples, either by states or communities or by private individuals. In almost all such cases it was necessary to obtain sanction for the foundation from the State; thus the inscription often takes the form of a decree of the people authorizing the foundation of the temple, and often giving some privileges to the founder or founders.

2. *Priests and Other Officials.*—Inscriptions give much information as to priests and other religious officials. There are in the first place lists of priests, some of them covering long periods and even going back to mythical times; there are also lists of

the treasurers and administrators, who were usually lay officials appointed for the purpose, either by election or by lot. The duties and privileges of priests are recorded in many inscriptions, and vary considerably from place to place. It is recorded, for instance, what portions of a victim at any sacrifice were to be received by the priest. In any important temple this must evidently have been far more than the priest or his family could consume, and accordingly it must have been sold, and so constituted a considerable source of income. Consequently a priesthood was an office well paid and much sought after; and we actually find in later Greek times, especially in Asia Minor, that priesthoods were frequently sold, under proper guarantees and with due sureties as to the duties being carried out. Sometimes a fee to the priest had to be paid in cash; in some cases a priest or priestess was allowed to take up a collection on certain days. On the other hand, the duties of a priest are often recorded; he had to see to the cleaning and care of the temple and its contents, to provide flowers and garlands for decorations and to supply the regular daily service. Sacrifices on great occasions were usually provided by the State, as also were important repairs; but in some cases a priest undertook these on his own account, and was honoured accordingly—for instance, by being allowed to inscribe his name in the restored temple.

Besides priests, we find many other officials of various ranks attached to temples and recorded in inscriptions. Some of these, especially those who were concerned with buildings or constructions, or with the inventories of temple treasures and the accounts of administration, were lay officials appointed by the State, as in the case of political officers. But many others had specialized sacerdotal functions; for instance, in many places there were *manteis* or prophets, often of special families with hereditary skill in divination; at Eleusis we find records of the hierophant, the torch-bearer, and others who took part in the celebration of the mysteries. At Olympia, in later Greek times, we find a remarkable list of officials, viz.: three priests, three libation pourers, two prophets, three custodians (of keys), a flute-player, an interpreter, a priest for the daily sacrifice, a secretary, a wine-pourer, three dancers at libations, a woodman (to supply wood for the sacrifices), and a steward and cook—the last no sinecure, in view of the numerous sacrificial feasts.

There were also many more menial offices in the service of temples which were carried out by slaves. Such slaves were often presented to the temple or acquired in some other way. There is a whole class of inscriptions, found on many sites, in which the sale of slaves to a temple or to the god of a temple is recorded. It is often difficult to know whether such slaves were intended for the service of a temple, or, on the other hand, such service was either purely formal or was not required at all, the sale to the temple being intended as fictitious, so as to enable a slave to acquire his own freedom and at the same time to secure the protection of the god in his free status.

3. *Ritual.*—The ritual appropriate to different divinities and temples varied greatly from place to place; and it was, therefore, necessary or desirable to set up notices in all public places of worship for the information and guidance of worshippers. The commonest and most essential act of worship was sacrifice; an example of the simplest form of prescription is to be seen in the inscription on the relief from Thasos in the Louvre:—"To the Nymphs and to Apollo the leader of the Nymphs, the worshipper may, if he so choose, sacrifice a male and a female victim. It is not permissible to offer a sheep or a pig. No paean is sung. To the Graces it is not permissible to offer a goat or a pig."

It is to be noticed that this order of service contains a prohibition as well as a prescription. Such prohibitions are frequent, and often relate to the need of ceremonial purity in all worshippers entering a sacred precinct. They must for a certain time have abstained from certain prescribed means of pollution, varying from place to place. The officials are sometimes ordered to erect notices giving information on this point; for instance, at the precinct of Alectrona at Ialysus, it was prescribed that "no horse, ass, mule, nor any other animal with a bushy tail should enter, and that nobody should bring such animals in or wear

shoes or any article produced from pigs. There is also a fine for driving in sheep." Other precincts were protected in a more general manner from any invasion or violation. It was prohibited to cut wood or to remove earth and stones, or to drive any beasts into some precincts; the right of erecting booths was either restricted or denied altogether. Sometimes more detailed prescriptions are given for the whole organization of a festival; thus, at Andania, in Messenia, the arrangements for the celebration of the local Eleusinia, the dress of the participants, the officials and policing, are very fully described. Similarly, in the hall of the Iobacchi, at Athens, the order of proceedings, the officers and the characters in the sacred play, and various administrative details are ordered.

When there is any doubt about any ritual or procedure, divination is often resorted to, and the results of such divination are recorded in inscriptions as a guidance for the future; it was also a common practice to consult Delphi or some other oracle in doubtful or difficult cases; there the exact method of procedure is sometimes recorded, as well as the response of the oracle. Forms of worship are often prescribed or recorded, especially hymns, which are sometimes inscribed together with their musical notation. The performance of songs or hymns and dances are also matters of constant reference, especially in connection with lyrical or musical contests; the victorious band or performer often dedicated the prize in honour of the god. A special form of contest was that in dramatic performances, of which many records have survived, both from Athens and from many other parts of the Greek world. The regulation of athletic festivals, and the records of victors in their contests, also form a numerous class of inscriptions. As regards mysteries, though there are numerous regulations affecting the arrangement of celebrations and the conduct of those participating, there is, as was to be expected, very little concerning the actual performances.

Another interesting phase of Greek religion known to us mainly from inscriptions is offered by the shrines of healing. The most notable of these is the precinct of Asclepius at Epidaurus. Here have been found, on large slabs of inscription, compiled, in all probability, from earlier documents, lists of the cures effected by Apollo and Asclepius. The cures are of the most varied kinds, from painful diseases or surgical cases to a lost boy and a broken cup. The formula is in almost all cases the same: the consultant comes to Epidaurus, sleeps in the *abaton*, has dreams or sees visions, and comes out whole. In later times, when such faith-healing had probably become less efficacious, elaborate prescriptions of diet and hygiene are recorded.

A special form of prayer consists of curses, which were often buried in the ground, probably with the intent to reach the infernal gods. Such curses often give the reason for their being made, usually some injury done to the author of the curse; sometimes they devote the offender to the infernal gods.

4. *Private Associations for Religious Purposes.*—Another element in Greek religion which is known to us almost exclusively by means of inscriptions, is to be found in the religious associations that existed in many Greek cities, apart from the organization of state religion, though sometimes recognized by it. These associations had each its own regulations, which were duly recorded in inscriptions; they varied greatly both in purpose and in character. Many of them had a definitely religious purpose, in the worship of certain gods; sometimes an alien community was given special permission to worship its own god or gods in its own way. Other associations were more social in character and served as clubs, or as burial societies. A remarkable feature about such associations is that the lists of members of many of them include the names of women and of slaves, thus contrasting with the civic basis of established religion in Greece, and anticipating a religion in which "there is neither Jew nor Greek, there is neither bond nor free, there is neither male nor female."

(b) *Political and Social.*—1. *Codes of Law and Regulations.*—Ancient writers state that the earliest laws of Athens were inscribed upon tablets of wood, put together in a pyramidal shape. These, owing to their material, have perished; but we have some very early codes of law preserved on stone, notably at Gortyna

in Crete. Here an inscription of great length is incised on the slabs of a theatre-shaped structure in 12 columns of 50 lines each; it is mainly concerned with the law of inheritance, adoption, etc. Doubtless similar inscriptions were set up in many places in Greece. An interesting series of inscriptions deals with the conditions under which colonists were sent out from various cities, and the measures that were taken to secure their rights as citizens. A bronze tablet records in some detail the arrangements of this sort made when the Locrians established a colony in Naupactus; another inscription relates to the Athenian colonization of Salamis, in the 6th century B.C.

2. *Decrees of People and Rulers, later of Kings and Emperors.*—A very large number of inscriptions are in the form of decrees of various cities and peoples, even when their subject matter suggests that they should be classified under other headings. Almost all legislative and many administrative measures take this form; often a decree prescribes how and where the inscription should be set up. The formulae and preambles of such decrees vary considerably from place to place, and from period to period. Those of Athens are by far the most exactly known, owing to the immense number that have been discovered; and they are so strictly stereotyped that they can be classified with the precision of algebraical formulae, and often dated to within a few years by this test alone. Very full lists for this purpose have been drawn up by Prof. W. Larfeld, in his work on the subject. It is usual to record the year (by the name of the eponymus archon), the day of the month and of the prytany (or presiding commission according to tribes), various secretaries, the presiding officials and the proposer of the decree. It is also stated whether the resolution is passed by the senate (*Boule*) or the assembly of the people (*Ecclesia*), or both. The circumstances or the reason of the resolution are then given, and finally the decision itself. Some other cities followed Athens in the form of their decrees, with such local variations as were required; others were more independent in their development, and different magistracies or forms of government had various results. In the Hellenistic age, and later, the forms of independent government were, to a great extent, kept up, though little real power remained with the people. On the other hand it is a common thing to find letters from kings, and later from Roman emperors, inscribed and set up in public places.

3. *Public Accounts, Treasure Lists, Building Inscriptions.*—It was customary to inscribe on stone all records of the receipt, custody and expenditure of public money or treasure, so that any citizen could verify for himself the safety and due control of the State in all financial matters. As in the case of temple accounts, it was usual for each temporary board of officials to render to their successors an account of their stewardship, and of the resources and treasures which they handed over. In all cases of public works, the expenditure was ordered by the State, and detailed reports were drawn up and inscribed on stone at intervals while the work was being carried out. In many cases there is a detailed specification of building work which makes it possible, not only to realize all the technical details and processes employed, but also the whole plan and structure of a building. A notable instance is the arsenal of Philon at the Peiraeus which has been completely reconstructed on paper by architects from the building specification. In the case of the Erechtheum, we have not only a detailed report on the unfinished state of the building in 409 B.C., but also accounts of expenditure and payments to the workmen employed in finishing it. Similar accounts have been preserved of the building of the Parthenon, spread over 15 years; in the case of both the Parthenon and the Erechtheum, there are included the payments made to those who made the sculptures.

Naval and military expenditure is also very fully accounted for; among other information there are records of the galley-slips at the different harbours of the Peiraeus, and of the ships of the Athenian navy, with their names and condition. In short, there is no department of state economy and financial administration that is not abundantly illustrated by the record of inscriptions.

Tribute Lists.—A set of records of high historical value are the

tribute lists, recording the quota paid to Athens by her subject allies during the 5th century B.C. These throw much light on her relations with them at various periods. (See DELIAN LEAGUE.)

4. *Ephebic Inscriptions.*—An institution as to which our knowledge is mainly derived from inscriptions is the ephebic system at Athens. There are not only records of lists of ephebi and of their guardians and instructors, but also decrees in honour of their services, especially in taking their due part in religious and other ceremonies, and resolutions of the ephebi themselves in honour of their officials. It is possible to trace in the inscriptions, which range over several centuries, how what was originally a system of physical and military training for Athenian youths from the age of 18 to 20, with outpost and police duties, was gradually transformed. In later times there were added to the instructors in military exercises others who gave lectures on what we should now call arts and science subjects; so that in the Hellenistic and Roman times, when youths from all parts of the civilized world flocked to Athens as an intellectual centre, the ephebic system became a kind of cosmopolitan university.

5. *Treaties and Political and Commercial Agreements; Arbitration, etc.*—In addition to inscriptions which are concerned with the internal affairs of various cities, there are many others recording treaties or other agreements of an international character between various cities and states. These were incised on bronze or stone, and set up in places of public resort in the cities concerned, or in common religious centres such as Olympia and Delphi. The simplest form of treaty is merely an alliance for a certain term of years, usually with some penalty for any breach of the conditions. Often an oath was prescribed, to be taken by representatives on each side; it was also not unusual to appeal to the god in whose temple the treaty was exhibited. In other cases a list of gods by whom the two parties must swear is prescribed. Commercial clauses were sometimes added to treaties of alliance, and commercial treaties are also found, agreeing as to the export and import of merchandise and other things. In later days, especially in the time of the Hellenistic kings, treaties tend to become more complicated and detailed in their provisions.

Another series of records of great historical interest is concerned with arbitration between various states on various questions, mainly concerned with frontiers. In cases of dispute it was not uncommon for the two disputants to appoint a third party as arbitrator. Sometimes this third party was another State, sometimes a specified number of individuals. Thus, in a frontier dispute between Corinth and Epidaurus, 151 citizens of Megara were appointed by name to arbitrate, and when the decision was disputed, 31 from among them revised or confirmed it. In all such cases it was the custom for a full record to be preserved on stone and set up in the places concerned. In this case the initiative in referring the matter to arbitration came from the Achaean League.

6. *Proxenia Decrees.*—A very large class of inscriptions deals with the institution of *proxenia*. According to this a citizen of any State might be appointed *proxenos* of another State; his duties would then be to offer help and hospitality to any citizen of that other State who might be visiting his city, and to assist him in any dispute or in securing his legal rights. The office has been compared to the modern appointment of consuls, with the essential difference that the *proxenos* is always a citizen of the state in which he resides, not of that whose citizens and interests he assists. The decrees upon this matter frequently record the appointment of a *proxenos*, and the conferring on him of certain benefits and privileges in return for his services; they also contain resolutions of thanks from the city served by the *proxenos*, and record honours consequently conferred upon him.

7. *Honours and Privileges Given to Individuals.*—This class of inscription is in form not unlike the last, except that the honours recorded are given for all sorts of services, private and public, to the State and to individuals. A frequent addition is an invitation to dine in the Prytaneum at Athens. Some are inscribed on the bases of statues set up to the recipient. In early times these inscriptions are usually brief and simple. The bust of Pericles on the Acropolis held nothing but the names of Pericles himself and of the

sculptor Cresilas. Later it became usual to give, in some detail, the reasons for the honours awarded; and in Hellenistic and Roman times, these became more and more detailed and fulsome in laudatory detail.

8. *Signatures of Artists.*—These inscriptions are of special interest as throwing much light upon the history of art. The artist's name was usually, especially in earlier times, carved upon the base or pedestal of a statue, and consequently was easily separated from it if the statue was carried off or destroyed. A case where both statue and pedestal are preserved is offered by the Victory, signed on its pedestal by Paeonius at Olympia. Occasionally, and more frequently in later times, the artist's signature was carved upon some portion of the statue itself. But in later copies of well-known works, it has to be considered whether the name is that of the original artist or of the copyist who reproduced his work.

A special class of artists' signatures is offered by the names signed by Attic and other vase painters upon their vases. These have been made the basis of a minute historical and stylistic study of the work of these painters, and unsigned vases also have been grouped with the signed ones, so as to make an exact and detailed record of this branch of Greek artistic production.

9. *Historical Records.*—The great majority of these fall into one of the classes already referred to. But there are some instances in which an inscription is set up merely as a record. For instance, a victor in athletic or other contests may set up a list of his victories. The most famous historical record is the autobiographical account of the deeds and administration of Augustus, which was reproduced and set up in many places; it is generally known as the Monumentum Ancyranum, because the most complete copy of it was found at Ancyra. The Marmor Parium at Oxford, found in Paros, is a chronological record of Greek history, probably made for educational purposes, and valuable as giving the traditional dates of events from the earliest time down.

10. *Tombs and Epitaphs.*—This is by far the most numerous class of inscriptions, both Greek and Latin. In early times there is often no record beyond the name of the deceased in Athens, often with the name of his father and his deme. Sometimes a word or two of conventional praise is added, such as "a good and wise man." Occasionally the circumstances of death are alluded to, especially if it took place in battle or at sea. Such epitaphs were frequently in metrical form, usually either hexameters or elegiacs. Many of them have been collected, and they form an interesting addition to the Greek anthology. In later times it becomes usual to give more elaborate praise of the deceased; but this is hardly ever so detailed and fulsome as on more modern tombstones. The age and other facts about the deceased are occasionally given, but not nearly so often as on Latin tombstones, which offer valuable statistical information in this respect.

LATIN INSCRIPTIONS

Latin inscriptions may be classified on much the same lines as Greek; but certain broad distinctions may be drawn at the outset. They are generally more standardized as to form and as to content, not only in Rome and Italy, but also throughout the provinces of the Roman empire. One of the chief difficulties in deciphering Latin inscriptions lies in the very extensive use of initials and abbreviations. These are of great number and variety, and while some of them can be easily interpreted as belonging to well-known formulae, others offer considerable difficulty, especially to the inexperienced student. A mere list of such initials and abbreviations occupies 68 pages in R. Cagnat's *Cours d'Épigraphie Latine*: a selection is given in this work in the article ABBREVIATION. Often the same initial may have many different meanings according to the context. Some common formulae such as V.S.L.M. (*votum solvit libens merito*), or H.M.H.N.S. (*hoc monumentum heredem non sequetur*) offer little difficulty, but there are many which are not so obvious and leave room for conjecture. Often the only way to determine the meaning is to search through a list of initials, such as those given by Cagnat, until a formula is found which fits the context.

Most of what has been said about Greek inscriptions applies

to Roman also. The commonest materials in this case also are stone, marble and bronze; but a more extensive use is made of stamped bricks and tiles, which are often of historical value as identifying and dating a building or other construction. The same applies to leaden water pipes which frequently bear dates and names of officials. Terra-cotta lamps also frequently have their makers' names and other information stamped upon them. Arms, and especially shields, sometimes bear the name and corps of their owners. Leaden discs were also used, to serve the same purpose as modern identification discs. Inscriptions are also found on sling bullets—Roman as well as Greek; there are also numerous classes of *tesserae* or tickets of admission to theatres or other shows.

As regards the contents of inscriptions, there must evidently be a considerable difference between the records of a number of independent city states and an empire including almost all the civilized world; but municipalities maintained much of their independent traditions in Roman times, and consequently their inscriptions often follow the old formulae.

The classification of Roman inscriptions may, therefore, follow the same lines as the Greek, except that certain categories are absent, and that some others, not found in Greek, are of considerable importance.

(a) **Religious.**—1. *Dedications and Foundations of Temples, etc.*—These are very numerous; and the custom of placing the name of the dedicant in a conspicuous place on the building was prevalent, especially in the case of dedications by emperors or officials, or by public bodies. Restoration or repair was often recorded in the same manner. In the case of small objects the dedication is usually simple in form; it usually contains the name of the god or other recipient and of the donor, and a common formula is D.D. (*dediit, donavit*), often with additions such as L.M. (*libens merito*). Such dedications are often the result of a vow, and V.S. (*votum solvit*) is therefore often added. Bequests made under the wills of rich citizens are frequently recorded by inscriptions; these might either be for religious or for social purposes.

2. *Priests and Officials.*—A priesthood was frequently a political office, and consequently is mentioned along with political honours in the list of a man's distinctions. The priesthoods that a man had held are usually mentioned first in inscriptions, before his civil offices and distinctions. Religious offices, as well as civil, were restricted to certain classes, the highest to those of senatorial rank, the next to those of equestrian status; many minor offices, both in Rome and in the provinces, are enumerated in their due order.

3. *Regulations as to Religion and Cult.*—Among the most interesting of these is the ancient song and accompanying dance performed by the priests known as the Arval Brothers. This is, however, not in the form of a ritual prescription, but a detailed record of the due performance of the rite. An important class of documents is the series of calendars that have been found in Rome and in various Italian towns. These give notice of religious festivals and anniversaries, and also of the days available for various purposes.

4. *Colleges.*—The various colleges for religious purposes were very numerous. Many of them, both in Rome and Italy, and in provincial municipalities, were of the nature of priesthoods. Some were regarded as offices of high distinction, and were open only to men of senatorial rank; among these were the Augurs, the Fetiales, the Salii; also the Sodales Divorum Augustorum in imperial times. The records of these colleges sometimes give no information beyond the names of members, but these are often of considerable interest. Haruspices and Luperci were of equestrian rank.

(b) **Political and Social.**—1. *Codes of Law and Regulations.*—Our information as to these is not mainly drawn from inscriptions and, therefore, they need not here be considered. On the other hand the word *lex* (law) is usually applied to all decrees of the Senate or other bodies, whether of legislative or of administrative character. It is, therefore, best to consider all together under the heading of public decrees.

2. *Laws and Plebiscites, Senatus Consulta, Decrees of Magistrates or later of Emperors.*—A certain number of these dating from republican times, are of considerable interest. One of the earliest relates to the prohibition of Bacchanalian orgies in Italy; it takes the form of a message from the magistrates, stating the authority on which they acted. Laws all follow a fixed formula, according to the body which has passed them. First there is a statement that the legislative body was consulted by the appropriate magistrate in due form; then follows the text of the law; and finally the sanction, the statement that the law was passed. In decrees of the Senate the formula differed somewhat. They began with a preamble giving the names of the consulting magistrates, the place and conditions of the meeting; then came the subject submitted for decision, ending with the formula QDERFP (*quid de ea re fieri placeret*); then came the decision of the Senate, opening with DERIC (*de ea re ita censuerunt*). C. is added at the end, to indicate that the decree was passed. In imperial times, the emperor sometimes addressed a speech to the Senate, advising them to pass certain resolutions, or else, especially in later times, gave orders or instructions directly, either on his own initiative or in response to questions or references. The number and variety of such orders is such that no classification of them can be given here. One of the most famous is the edict of Diocletian, fixing the prices of all commodities. Copies of this in Greek as well as in Latin, have been found in various parts of the Roman empire.

3. *Records of Building, etc.*—A very large number of inscriptions record the building or repair of public buildings by private individuals, by magistrates, Roman or provincial, and by emperors. In addition to the dedication of temples, we find inscriptions recording the construction of aqueducts, roads, especially on milestones, baths, basilicas, porticos and many other works of public utility. In inscriptions of early period, often nothing is given but the name of the person who built or restored the edifice, and a statement that he had done so. But later it was usual to give more detail as to the motive of the building, the name of the emperor or a magistrate giving the date, the authority for the building, and the names and distinctions of the builders; then follows a description of the building, the source of the expenditure (e.g. S.P., *sua pecunia*), and finally the appropriate verb for the work done, whether building, restoring, enlarging or otherwise improving. Other details are sometimes added, such as the name of the man under whose direction the work was done.

4. *Military Documents.*—These vary greatly in content, and are among the most important documents concerning the administration of the Roman empire. "They are numerous and of all sorts—tombstones of every degree, lists of soldiers' burial clubs, certificates of discharge from service, schedules of time-expired men, dedications of altars, records of building or of engineering works accomplished. The facts directly commemorated are rarely important." But when the information from hundreds of such inscriptions is collected together, "you can trace the whole policy of the imperial Government in the matter of recruiting, to what extent and till what date legionaries were raised in Italy; what contingents for various branches of the service were drawn from the provinces, and which provinces provided most; how far provincials garrisoned their own countries, and which of them, like the British recruits, were sent as a measure of precaution to serve elsewhere; or, finally, at what epoch the empire grew weak enough to require the enlistment of barbarians from beyond its frontiers." (F. Haverfield, in *Authority and Archaeology*, p. 314.)

5. *Treaties and Agreements.*—There were many treaties between Rome and other states in republican times; but we do not, as a rule, owe our knowledge of these to inscriptions, which are very rare in this earlier period. In imperial times, to which most Latin inscriptions belong, international relations were subject to the universal domination of Rome, and consequently the documents relating to them are concerned with reference to the central authority, and often take the form of orders from the Emperor.

6. *The custom of proxeny* belonged to Greece. What most nearly corresponded to it in Roman times was the adoption of

some distinguished Roman as its *patron*, by a city or state. The relation was then recorded, usually on a bronze tablet placed in some conspicuous position in the town concerned. The patron probably also kept a copy in his house, or had a portable tablet which would ensure his recognition and reception.

7. *Honorary*.—Honorary inscriptions are extremely common in all parts of the Roman world. Sometimes they are placed on the bases of statues, sometimes in documents set up to record some particular benefaction or the construction of some public work. The offices held by the person commemorated, and the distinctions conferred upon him are enumerated in a regularly established order (*cursus honorum*), either beginning with the lower and proceeding step by step to the higher, or in reverse order with the highest first. Religious and priestly offices are usually mentioned before civil and political ones. These might be exercised either in Rome itself, or in the various municipalities of the empire. There was also a distinction drawn between offices that might be held only by persons of senatorial rank, those that were assigned to persons of equestrian rank, and those of a less distinguished kind. It follows that when only a portion of an inscription has been found, it is often possible to restore the whole in accordance with the accepted order.

8. *Signatures of Artists*.—When these are attached to statues, it is sometimes doubtful whether the name is that of the man who actually made the statue, or of the master whose work it reproduces. Thus there are two well-known copies of a statue of Hercules by Lysippus, of which one is said to be the work of Lysippus, and the other states that it was made by Glycon. Another kind of artist's or artificer's signature that is commoner in Roman times is to be found in the signatures of potters upon lamps and various kinds of vessels; they are usually impressed on the mould and stand out in relief on the terra-cotta or other material. These are of interest as giving much information as to the commercial spread of various kinds of handicrafts, and also as to the conditions under which they were manufactured.

9. *Historical Records*.—Many of these inscriptions might well be assigned to one of the categories already considered. But there are some which were expressly made to commemorate an important event, or to preserve a record. Among the most interesting is the inscription of the Columna Rostrata in Rome, which records the great naval victory of Duilius over the Carthaginians; this, however, is not the original, but a later and somewhat modified version. A document of high importance is a summary of the life and achievements of Augustus, already mentioned, and known as the Monumentum Ancyranum. The various sets of Fasti constituted a record of the names of consuls, and other magistrates or high officials, and also of the triumphs accorded to conquering generals.

10. *Inscriptions on Tombs*.—These are probably the most numerous of all classes of inscriptions; and though many of them are of no great individual interest, they convey, when taken collectively, much valuable information as to the distribution and transference of population, as to trades and professions, as to health and longevity, and as to many other conditions of ancient life. The most interesting early series is that on the tombs of the Scipios at Rome, recording, mostly in Saturnian metre, the exploits and distinctions of the various members of that family.

About the end of the republic and the beginning of the empire, it became customary to head a tombstone with the letters D.M. or D.M.S. (*Dis Manibus sacrum*), thus consecrating the tomb to the deceased as having become members of the body of ghosts or spirits of the dead. These are followed by the name of the deceased, usually with his father's name and his tribe, by his honours and distinctions, sometimes by a record of his age. The inscription often concludes with H.I. (*Hic iacet*), or some similar formula, and also, frequently, with a statement of boundaries and a prohibition of violation or further use—for instance, H.M.H.N.S. (*hoc monumentum heredem non sequetur*, this monument is not to pass to the heir). The person who has erected the monument and his relation to the deceased are often stated; or if a man has prepared the tomb in his lifetime, this also may be stated, V.S.F. (*vivus sibi fecit*). But it is obvious that there is an

immense variety in the information that either a man himself or his friends may wish to record.

11. *Milestones and Boundaries*.—Milestones (*miliaria*) have already been referred to, and may be regarded as records of the building of roads. Boundary stones (*termini*) are frequently found, both of public and private property. A well-known instance is offered by those set up by the commissioners called III. viri A.I.A. (*agris iudicandis adsignandis*) in the time of the Gracchi.

THE STUDY OF INSCRIPTIONS

Inscriptions were studied and quoted by authors in ancient times, by orators and by historians—notably by Thucydides and Polybius—as records of political, economic and social interest; they also contributed to the history of art, and Polemon had the nick-name of *stelokopas* given him for his studies of such documents. His work is now lost. Some of the great scholars of the Renaissance were interested both in Greek and Roman inscriptions. But the gigantic task of collecting together all known Greek inscriptions was first attempted by A. Boeckh, in the *Corpus Inscriptionum Graecarum* (4 vols., 1825-40). This has been superseded by *Inscriptiones Graecae* (Berlin) in 14 volumes and many parts, arranged geographically. This great work is still in progress. Inscriptions prior to 403 B.C. are collected in Roehl, *Inscriptiones Graecae Antiquissimae*. Convenient selections are W. Dittenberger, *Sylloge Inscriptionum Graecarum* (4 vols. 3rd ed., 1924), and *Orientalis Graeca Inscriptiones selectae* (2 vols. 1904-05); Michel, *Recueil d'Inscriptions Grecques* (1900); Hicks and Hill, *Greek Historical Inscriptions* (2nd ed. 1901); *Inscriptiones Graecae ad Res Romanas pertinentes* (Paris, Académie; 4 vols. 1891-1927); *Sammlung der Griechischen Dialekt-Inschriften* (Göttingen, 1884); Dureste and others, *Recueil des Inscriptions Juridiques Grecques* (1891); Kaibel, *Epigrammata Graeca et Lapidibus Collecta* (1878).

For formal introduction to the study, S. Reinach, *Traité d'Epigraphie Grecque* (1885; the introductory chapters translated from C. T. Newton, *Essays in Art and Archaeology*, 1880); E. S. Roberts, *Introduction to Greek Epigraphy* (vol. 1, 1887, vol. 2, with E. A. Gardner, *The Inscriptions of Attica*, 1905); W. Larfeld, *Griechische Epigraphie* (1892); *Handbuch der Griechischen Epigraphie* (1898); O. Kern, *Inscriptiones Graecae* (1913, photographic facsimiles).

In addition there are many publications of the inscriptions of special sites or localities, notably those from great excavations like those of Olympia and Delphi, or in museums, such as the British Museum Inscriptions.

For Latin inscriptions, the chief publication is the *Corpus Inscriptionum Latinarum* (Berlin—in progress); the volumes are arranged geographically; supplements are issued as *Ephemeris Epigraphica*. Convenient selections are those of Wilmanns, *Exempla Inscriptionum Latinarum* (1872), and of Dessau, *Inscriptiones Latinae* (3 vols. 1892-1916). An introduction to the study is R. Cagnat, *Cours d'Epigraphie Latine* (1890), having useful tables of initials, abbreviations and formulae. (E. Gr.)

INSECT BITES AND STINGS. Insects may be the cause of disease or of morbid conditions in man in several different ways: (1) by living on his skin or hair, as in the case of three varieties of pediculi or lice (the head-louse, the body-louse, the crab-louse); or in his skin, as with the itch-insect (though this is strictly not an insect at all but a spider-like parasite), or with the tropical chigger, jigger or sand flea; (2) by depositing their eggs on the skin or mucous membrane, or on wounds, whence the larvae find their way below the surface, usually by boring or burrowing, as is the case with several tropical flies; (3) by being the instrument of transferring a bacterial infection to man from some other animal, as is the case with the rat flea in plague, or by taking part as host in the life-cycle of a spirochaete or a protozoon and passing the parasite on to man, as is done by certain mosquitoes in yellow fever or in malaria; (4) by the direct and immediate effects of their bite or sting. It is with this last method only that the present article is concerned.

In Great Britain and the United States, as in most other countries, such bites and stings are exceedingly common, the most frequent biting insects being the common flea, the bed-bug, gnats

and mosquitoes, and the most frequent stinging insects being the wasp, the bee, the hornet and the ant. It should be realized, too, that the effects of the louse are due not merely to its presence, as mentioned above, but to its actual bite.

The consequences of these bites and stings are well known, very few persons escaping some personal experience thereof, though susceptibility varies widely in different persons. Local irritation may be extreme, and the skin lesion produced may vary from a small reddened or erythematous patch or a tiny papule, to large urticarial or nettle-rash wheals, or even to a spreading cellulitis or inflammation of the tissues under the skin. These effects, usually pass off completely in a few hours or at most a day or two. Occasionally, however, dangerous developments occur.

The conditions most likely to lead to such developments are: (1) a very large number of stings, as when a swarm of angry bees settles on the body; (2) the lesion being on a mucous surface such as the tongue, the palate or the pharynx; (3) the supervention of some local complication such as erysipelatous or other streptococcal infection, or the direct transmission of some form of septic poisoning as by the bite of a fly which has been feeding on putrid material. In all such cases skilled surgical aid should at once be sought, as in extreme instances death has occasionally resulted and urgent measures may be necessary to deal with the situation.

Treatment.—The poison injected with an insect sting is, at least in many species, formed by a mixture of the secretions of two glands, one of which is acid (formic acid) and the other of which is alkaline. In most cases the acid predominates; hence weak alkaline solutions (soda or ammonia) are commonly effective in allaying the irritation. In some cases, however, especially, it is said, with the sting of some wasps, the alkaline element is predominant and in such instances a weak acid lotion (such as diluted vinegar) gives most relief.

The most convenient substance to use to relieve the irritation of mosquito bites is moist toilet soap. Late experience shows that the so-called "chigger bites" or the irritation caused by the entrance of any larval mites into the skin are best treated with a phenol-camphor mixture known in medicine as camphora carbolisata.

As preventive measures when insects are prevalent, camphor, menthol, lavender and oil of eucalyptus appear to have some virtue; and skilful and assiduous campaigns against flies, mosquitoes and wasps have of late added greatly to the amenities of a number of localities. A good preventive lotion against mosquitoes is composed of one part oil of citronella, one part spirits of camphor and one-half part oil of cedar. (See BACTERIOLOGY; KALA-AZAR; PARASITOLOGY.) (H. B. B.)

INSECTICIDES, chemicals used for destroying insect pests. When employed to protect plants they may be applied in the form of wet sprays or as dusts; those most commonly used for this purpose include various arsenicals, nicotine, oil emulsions, soaps, caustic alkalis, etc. When it is desired to kill insects that may be present in a room, fumigation (*q.v.*) or the filling of the room with poisonous gases or vapours is resorted to. This method may also be used for plants by enclosing them in tents. Hydrogen cyanide, carbon disulphide and carbon tetrachloride are some examples of the chemicals employed in fumigation. (See ENTOMOLOGY, ECONOMIC: *Control Measures*; *Physico-chemical Methods*.)

INSECTIVORA, an order of placental mammals of small size, with a dentition adapted to an insect-diet. Nearly all members of this order are nocturnal and terrestrial, many, however, are fossorial or arboreal, and a few are aquatic. There are generally five toes, each terminating in a claw; the first toe is never opposable to the others in either the fore or hind limb. A full series of teeth, including temporary, or deciduous milk-molars is developed, and the cheek-teeth are crowned with sharp cusps as a rule. The typical number of teeth is 44, arranged as shown in the formula $i.\frac{3}{3}, c.\frac{1}{1}, p.\frac{4}{4}, m.\frac{8}{8}$; occasionally there is a fourth pair of molars, while the incisors may be reduced to two pairs above and one pair below. The skull is of a primitive type, with a small brain-case, tympanic bone generally ring-like instead of forming a bulla and vacuities are frequently present in the palate. With the exception of the African *Potamogale*, collar-

bones are always present, and a central bone is usually present in the carpus. The uterus is two-horned, the placenta, so far as is known, is deciduate and discoidal; the testes are abdominal or inguinal, and the teats usually numerous.

Representatives of this order are found throughout the temperate and tropical parts of both hemispheres, with the exception of South America (where only a few shrews have penetrated) and Australia.

The stomach is a simple, thin-walled sac; sometimes as in *Centetes*, the pyloric and oesophageal openings are close together. In the arboreal forms, which probably feed on vegetables as well as insects, most of the species possess a caecum.

Varieties of the Order.—All the members of the order appear to be highly prolific, the number of young varying from two to eight in the hedgehog, and from twelve to twenty-one in the Tenrec. Scent-glands exist in many species. In most shrews they occur on the sides of the body at a short distance behind the axilla, and their exudation is probably protective, as very few carnivorous animals will touch them. In both species of *Gymnura* and in *Potamogale* large pouches are situated on each side of the rectum, and discharge their secretions by ducts, opening in the first named genus in front of and in the latter within the margin of the vent. In the Tenrec similarly situated glands discharge by pores, opening at the bottom of deep pits.

If *Galeopithecus* and *Galeopterus* are accepted as members of the Insectivora then the order may be split into two suborders, the *Dermoptera* and the *Insectivora vera*. The former contains only the two genera *Galeopithecus* and *Galeopterus*. For further information on these two interesting genera see the articles GALEOPITHECUS and GALEOPTERUS.

Insectivora Vera.—The *Insectivora vera* may be divided into nine families, which fall into two groups. The first of these, containing the families *Tupaïidae* and *Macroscelididae*, is characterised by the full development of the union between the two halves of the pelvis. The orbit is either surrounded by bone (*Tupaïidae*) or is separated from the hinder part of the skull by a post-orbital process (*Macroscelididae*). Some authors regard the *Tupaïidae* as lowly organized members of the order Primates, but the present writer is quite unable to consider the genus *Tupaia* and its near relations *Anathana*, *Dendrogale*, *Urogale*, *Tana* and *Ptilocercus*, as representing anything more than a group of Insectivores. The *Tupaïidae*, which are confined to the Oriental region, are, however, in addition to the bony ring surrounding the orbit, distinguished by the large size of the brain. The dental formula is $I.\frac{2}{3}, C.\frac{1}{1}, P.\frac{3}{3}, M.\frac{3}{3}$. The *Tupaïas* or Tree-Shrews are in many ways very like squirrels; they are, however, distinguished by their pointed insectivorous faces and light coloured shoulder stripes. The typical genus contains a great number of species and subspecies. *T. ferruginea*, from the Malay Peninsula and Islands, is bright chestnut-brown in colour with an olive-brown face and tail; the majority of the members of this genus do not exceed 350 mm. in total length. *T. pictus*, of Borneo, is a very handsomely coloured Tree-Shrew, chestnut and olive above, with buff shoulder stripes and a black dorsal stripe. From the Rhio Archipelago comes a deep chestnut coloured form known as *T. castanea*. *T. minor* is a very small species from Borneo, with a hind-foot of only 28 mm., and a total length of about 280 mm.

The closely allied genus, *Anathana*, is distinguished from *Tupaia* by the inner sides of the ears being more hairy, the larger size of the lower lobe of the ear, and the coarser nasal reticulations. The species come from India and Borneo. The genus *Urogale*, allied to *Tupaia* and *Anathana*, contains but a single species *U. cylindura* from the Philippine Islands, in general dimensions and appearance about as in the smaller *Tupaïas*, the total length being 250 mm.

A number of handsomely coloured Tree-Shrews has recently been placed in the genus *Tana*. Included in this genus is a very brightly coloured species from Borneo and Sumatra, *T. tana*. *T. dorsalis*, from Borneo, is a smaller species, with a well-marked black dorsal stripe extending from the crown of the head to the base of the tail. The smallest members of this family are included in the genus *Dendrogale*, the total length not exceeding

235 mm. These pigmy Tree-Shrews come from Annam, Cochin China, Cambodia and Siam.

The asiatic Penta-tailed Tree-Shrew (*Ptilocercus lowi*) is usually included in this family, although it differs very markedly from all the other genera. The tail is very long, with the proximal two-thirds naked, and the remaining third furnished with a feather-like fringe. This species, the only representative of the genus, is found in Borneo, Sumatra and parts of the Malay Archipelago.

THE MACROSCOLIDIDAE

In Africa the *Tupaia*s are represented by the Jumping and Elephant Shrews constituting the family *Macroscelididae*, distinguished from the *Tupaiidae* by the absence of the bony rings around the orbits, the latter being separated from the hinder part of the skull merely by the post-orbital processes of the frontal bones. Further, the tarsus is markedly elongated and the lower ends of tibia and fibula are joined. Dental formula $i.\frac{3}{2}, c.\frac{1}{1}, p.\frac{4}{4}, m.\frac{2}{2}$. The members of this family leap like gerbils or jerboas. The *Macroscelididae* may be considered to contain seven genera:—(1) *Macroscelides*, or Jumping Shrews, containing two South African species *M. proboscideus* from Cape Colony and the Orange Free State, and *M. melanotis* from Namaqualand; in this genus the lower molars are two in number and the auditory bullae much enlarged. (2) *Elephantulus* containing the Jumping Shrews of North, East and South Africa in which the lower molars are two in number, but the auditory bullae are normal, not enlarged. In size about equal to the foregoing genus. The various species extend from Morocco and Algeria (*E. roseti*) southwards to Somaliland, East and South Africa. (3) *Nasilio*, or the Short-Nosed Jumping Shrews, with three lower molars and normal auditory bullae. Like the two allied genera, *Macroscelides* and *Elephantulus*, these Jumping Shrews are diurnal. The genus extends as far north as Angola in the west and Kenya Colony in the east. (4) *Petrodromus*, the 4-Toed Jumping Shrews, are distinguished from the foregoing genera in having only 4 instead of 5 toes to each front foot; the dimensions are considerably larger and the coat quite different in colour, being pale olive-green on the flanks and rufous on the back (*P. tetradactylus*, South Africa). The tail is long and clothed in short normal hairs. (5) *Mesoctenus*, closely allied to *Petrodromus*, but distinguished by the hairs on the underside of the tail being slightly bulbous at their ends; this genus includes two species *M. rovumae* (Rovuma) and *M. nigriseta* from East Africa. (6) *Cercotenus*, in which the bulbous, or club-shaped hairs on the underside of the tail are still more developed, two species are recognized. *C. sultan* from Zanzibar, Tanganyika Territory, and Kenya Colony, and *C. schwanni* from Portuguese East Africa. (7) *Rhynchocyon*, the Long Nosed Elephant Shrews, in which the reduction in the number of toes is carried still further, there being only four toes to each foot. In this genus the snout is much longer, the size of the body considerably greater, and the tarsus still more elongated. The dental formula is $i.\frac{1 \text{ or } 0}{2}, c.\frac{1}{1}, p.\frac{4}{4}, m.\frac{3}{3}$. It has been proposed to divide the genus into two subgenera, the typical one containing the chess-board patterned species (*R. cirnei*, *reichardi*, *claudi* and *stulhmanni*) and *Rhinonax* including *R. chrysopygus* and *R. petersi* and its allies. Some of these Elephant Shrews are very handsomely coloured, *R. cirnei* from Nyasaland, has the posterior part of its back marked with rows of alternate dark and light blotches, giving a chess-board effect. The apical portion of the tail is always white. In the subgenus *Rhinonax* equally bright colouring occurs; *R. (R.) petersi* comes from East Africa and Zanzibar. *R. (R.) chrysopygus* (East Africa) has the body, flanks and limbs deep maroon, and the rump bright orange-yellow coloured.

SECOND GROUP OF FAMILIES

In the second group of families, which contains all the remaining Insectivora, the pelvic symphysis is either lacking or formed merely by the epiphyses of the pubes; and the orbit and temporal region of the skull are confluent. With the exception of the *Talpidae* (true Moles) and *Chrysochloridae* (golden Moles) the tympanum is ring-like. The first representatives of this group

are the Moles, constituting the family *Talpidae*, in which the lower ends of the tibia and fibula are united, there is a descent of the testes, the tympanum forms a bladder-like bulla, the zygomatic or cheek-arch, although slender, is complete, there is no pelvic symphysis, the upper molars are five, and the first upper incisor is simple and the lower vertical. Most of the species are burrowing, but a few are aquatic; they have an exclusively animal diet. They are confined to temperate Europe, Asia and North America. Throughout the family the eyes are very small, and in some of the forms are covered with skin; the ears are short, and the fore-limbs are generally more or less modified for digging. The true Moles of the genus *Talpa* are the typical members of the first subfamily, the *Talpinae*, in which the clavicle and humerus are very short and broad, while there is an additional sickle-like bone on the inner side of the fore-foot which is very broad. The dental formula of the genus *Talpa* is $i.\frac{3}{3}, c.\frac{1}{1}, p.\frac{4}{4}, m.\frac{3}{3}$. *T. europea*, the Common European Mole, is widely distributed over Europe and western and central Asia; the eastern limits of its range are not known. *Parascaptor* is a closely related genus containing one species, *P. leucurus*, from Assam and the adjacent country; it is a small mole with a very short tail and long snout. The genus *Scaptochirus* is considered to contain three species from China; these moles possess very large fore-feet and short tails. Another closely allied genus is *Mogera*, which includes a few species of short-haired moles with short tails; dental formula $i.\frac{3}{3}, c.\frac{1}{1}, p.\frac{4}{4}, m.\frac{3}{3}$. These moles come from the Far East; *M. wogera*, from Japan, is a large, pale vandyke-brown coloured species.

There remain four North American genera of *Talpinae*:—(i.) *Scalops*, a genus with very large fore-feet and webbed toes; tail very short, slender and nearly naked, and ears and eyes quite small. *S. aquaticus*, the common mole of the eastern United States and of considerable importance as a fur-bearing animal, is found from Massachusetts to Minnesota and Colorado and southward to Florida and Texas. It is a pale sepia-coloured or slate-coloured mole, often tinged with brown, varying in length in the different sub-species, of which some 10 are recognized, from barely $5\frac{1}{2}$ in. to 8 in. and in colour from light drab to dark sepia and brown. (ii.) *Scapanus*, a genus with very broad hands, but with toes lacking webs; the tail is rather longer, thick and scantily haired, and the general colour of the body is darker, varying in winter in some forms to black. There are several species, all natives of the Pacific slope where they take the place of the common mole (*Scalops*) of the eastern United States, which they strongly resemble in their habits. *S. townsendi*, the best known of the group, comes from northern California, Oregon and Washington, where it is common between the Cascades and the Coast ranges. It is a large mole, 9 in. long and blackish in colour, with a plump body and a tail $1\frac{1}{2}$ in. long. *S. orarius*, about 7 in. long, with the body blackish or greyish in colour, occurs from northern California through Oregon and Washington to British Columbia. *S. latimanus*, similar or slightly larger in size but varying in colour from grey or drab to brown and black, is found from southern California to central Oregon; a larger grey form, var. *alpinus*, $7\frac{1}{2}$ in. long, occurs at Crater Lake. (iii.) *Parascalops*, is a smaller genus, with one species. *P. breweri*, the Hairy-tailed Mole, found in dry sandy soil from New Brunswick to Georgia and westward to Ohio; the body is blackish, often with brownish gloss; the tail is short, thick, compressed at the base, and very hairy; the toes are not webbed. (iv.) *Condylura*, the Star-nosed Mole, which is distinguished by the possession of a fringe of fleshy appendages around the extremity of the snout, 11 appendages on each side. Its general bodily size is about that of the common European mole, but the tail is much longer. The star-nosed mole is blackish in colour and about $7\frac{1}{2}$ in. long; the tail, which is about $2\frac{1}{2}$ in. long, is covered with coarse hair; and the toes are not webbed. One species only is recognized, *C. cristata*, the type locality of which is Pennsylvania; it occurs, but rather infrequently, in wet meadows and marshes from southern Labrador to south-eastern Manitoba southward to Georgia and Indiana, often leaving its burrows and running about on the surface.

Second Subfamily.—The second subfamily is the *Desmaninae* including a series of animals rather intermediate between Moles and Shrews, known as the Mole-Shrews. A number of genera has been described, the most important of which are the following:—(i.) *Urotrichus*, small shrew-like animals with long snouts, and hairy, almost bushy tails; fore-feet not markedly enlarged, but more so than in the Shrews. *U. talpoides* comes from Japan, from where a number of races have been described (head and body 90 mm., tail 25 mm.). (ii.) *Neurotrichus* contains a small shrew-like species, *N. gibbsi*, with large hands and a short hairy tail (head and body 110 mm., tail 36 mm.). (iii.) *Scaptonyx*, allied to *Neurotrichus*, with a more hairy tail and smaller fore-feet; the genus is restricted to China. (iv.) *Dymecodon*, contains but a single species, *D. pilirostris* from Japan; it is smaller than *Urotrichus* and has a proportionally longer, but less hairy tail (head and body 78 mm.; tail 40 mm.). (v.) *Uropsilus* a long-nosed, long-tailed genus, with small hands and feet; the tail is short-haired; *U. soricipes* hails from China. (vi.) *Rhynchonax*, contains a single species from Sze-Chuan, China, smaller than *Uropsilus* and darker in colour. (vii.) *Galemys* contains the Water Mole or Western Desman, from south-western France and the Italian Peninsula. This and the following species show marked adaptation to an aquatic life the toes being webbed and the tail long and flattened laterally. The snout is of considerable length, as also is the soft body fur which is otter-brown above, and yellowish-grey below. Dimensions of the species (*G. pyrenaeicus*):—head and body 131 mm., tail 145 mm., hind-foot 38. The last genus (9) *Desmana*, the Russian Desman (*D. moschata*) is very similar in form to *Galemys*, but much larger and more massive (total length 16 inches); it inhabits the streams and lakes of South-east Russia.

The Soricidae.—The next family, the *Soricidae* or Shrew-Mice, is closely related to the Moles, with which it is connected by some of the subfamily *Desmaninae*. The species are, however, distinguished by the ring-like tympanic, incompleteness of the zygomatic arch, and the forward direction of the first lower incisors. The majority are terrestrial, but a few are aquatic. There are no lower canines, and always six functional teeth on each side of the lower jaw; in some species an additional tooth occurs. In the typical genus *Sorex* the dental formula is as follows:— $i.\frac{3}{2}, c.\frac{1}{0}, p.\frac{1}{1}, m.\frac{3}{3}$; in this genus and its allies the teeth are tipped with brownish-red, in the *Crocidurine* section the teeth are wholly white. The members of the genus *Sorex* are widely spread over Europe, Asia (north of the Himalayas) and North America. The ears are well developed, the tail long and evenly haired, without the long hairs so characteristic of *Crocidura*. The typical species *S. araneus* is the Common Shrew-Mouse of Europe; it is distributed over the northern portions of Europe and Asia from England and Scotland eastward; southwards it reaches central Spain and Italy. As with so many British mammals it is absent from Ireland. (Head and body 65 to 80 mm.; tail 20–35 mm.; hind-foot 11–14.5 mm.). *S. minutus*, the Pygmy Shrew Mouse, is considerably smaller, measuring only about 52 mm. in length (head and body); found over the northern part of Eurasia from Ireland eastward and south as far as the Pyrenees and southern Italy. Over sixty species and subspecies of this genus have been described. In the genus *Soriculus* the openings of the male and female generative organs form with the anal orifice a shallow cloaca; in *Sorex* they are separate; dentition $i.\frac{3}{2}, c.\frac{1}{0}, p.\frac{1}{1}, m.\frac{3}{3}$. The longest tailed *Soriculus* is *S. irene*, from Sze-Chuan, in which the tail measures 87 mm.; and the head and body 62 mm. in length. Closely allied to *Soriculus* is a group of small Chinese Shrews belonging to the genus *Chodsigoa*, some species having a long tail (63 mm.) while others (*C. lamula*) have a fairly short tail (head and body 67 mm.; tail 54 mm.). *Notiosorex* (dentition $i.\frac{3}{2}, c.\frac{1}{0}, p.\frac{1}{1}, m.\frac{3}{3}$) contains a small species, *N. crawfordi* from New Mexico (head and body 85 mm.; tail 26 mm.; hind-foot 12 mm.); and *Blarina* is another short-tailed genus of American Shrews, some members of which are found in South and Central America; in size they are about equal to the Common European Shrew, but have a much shorter tail (*B. brevicauda*:—tail 26 mm.; dentition $i.\frac{4}{2}, c.\frac{1}{0}, p.\frac{1}{1}, m.\frac{3}{3}$).

The genus *Blarinella*, from Western China, is closely allied to the American *Blarina*; the tail is not quite so short and the ear not so rudimentary as in the latter genus. The teeth are all heavily pigmented. *B. quadratauda*:—head and body 69 mm.; tail 43 mm.; *B. griselda*, from Tao-chou, is smaller and has a shorter tail; dimensions:—head and body 63 mm.; tail 33 mm.; hind-foot 11 mm. *Neomys* is an aquatic genus of Shrews found over a large area of the Palaertic region north of the Mediterranean from Spain and England to the Caucasus and Asia Minor, northwards as far as Scandinavia. Dental formula, $i.\frac{3}{2}, c.\frac{1}{0}, p.\frac{1}{1}, m.\frac{3}{3}$. The fur is very soft and dark slatey-grey in colour; feet and tail fringed.

In the United States the *Soricidae* are represented by six genera. *Sorex*, with 20 species, includes *S. personatus*, the Common American Shrew, 4 in. long, found from New England to Tennessee and Alaska; *S. fumens*, the Smoky Shrew, of the north-eastern States, and *S. vagrans*, the Western Shrew, abundant from the Rocky Mountains westward. *Neosorex*, with 4 species, includes *N. albibarbis*, the Marsh Shrew, of eastern North America. *Microsorex*, with 2 species, includes *M. winnemauna*, of Virginia, only 3 in. long, the smallest American mammal. *Blarina*, with 2 species, includes *B. brevicauda*, the Mole-shrew, of the central and eastern states; *Cryptotis* contains 2 species, natives to the southern states, and *Notiosorex*, a single species found in the south-west.

The Shrews with white teeth are found in Europe, Asia and Africa. The short-haired, long-tailed Shrews of Africa with four upper unicuspid are grouped together in the genus *Sylvisorex*, in some the tail is much longer than the body (head and body 60 mm.; tail 85); in others, as in *S. lunaris* from Ruwenzori, the tail is about equal in length to the head and body. In the allied genus *Myosorex*, also from Africa, the tail is long and the fur soft and thick; the openings of the generative organs and vent, although close together, are distinct. *Surdisorax* is another white-toothed genus containing one or two species; *S. norae* is distinguished by its very short tail (head and body 92 mm.; tail 20 mm.; hind-foot 15 mm.), very soft, deep chocolate-coloured coat, and large fore-feet. It inhabits Kenya Colony. The typical genus of this group, *Crocidura*, or Musk Shrews, is found over nearly the whole of Africa and the warmer parts of Europe and Asia; a species has recently been described from the Scilly Isles. Dentition $i.\frac{3}{2}, c.\frac{1}{0}, p.\frac{1}{1}, m.\frac{3}{3}$. The generative openings form a short cloaca with the anal orifice. Tail long, with a number of long, rather bristly hairs in addition to the shorter normal hairs. Some of the largest and smallest members of this genus are found in Africa; the smallest Musk Shrew, probably the smallest mammal, is *C. pasha*, from the Sudan. The *Crocidurine* Shrews with an extra premolar (dentition, $i.\frac{3}{2}, c.\frac{1}{0}, p.\frac{2}{1}, m.\frac{3}{3}$) are considered to represent a distinct genus, *Pachyura*, which is found over Africa, the warmer parts of Asia, and Mediterranean region. The members of this group all have the typical *Crocidurine* tails, with the long bristle-like hairs. *Praesorex goliath* is a giant shrew from the Cameroons (head and body 170 mm.; tail 102 mm.; hind-foot 25 mm.) related to the *Crocidura* but distinguished by its longer and harsher coat. In *Solisorex pearsoni*, another large form, the tail is shorter (66 mm.) and the fur softer and greyer. *Scutisorex* includes the "Tin-hatted Shrews" from Uganda and the Eastern Congo. The skull of this species has enormously developed lambdoid crests which extend backwards and are continuous with a posterior extension of the lateral temporal crests (head and body 143 mm.; tail 77 mm.; hind-foot 20 mm.).

Anourosorex.—*Anourosorex* is an allied genus containing but a single species, *A. squamipes*, a small mole-coloured shrew with a very short tail (head and body 83 mm.; tail 16 mm.; hind-foot 15 mm.). This genus, which inhabits Sze-chuan and Tibet, is distinguished from the closely related genus *Diplomesodon*, from the Kirghiz Steppes, by the soles of the hindfeet being scaly, not hairy. The latter genus, which also contains only one species, *D. pulchellus*, is further distinguished by its longer tail. Lastly there are two Asiatic mountain aquatic genera:—(i.) *Chimarroale* from Kashmir, Sikkim, and country around Darjeeling,

distinguished by its long tail with an inferior fringe of elongated hairs; the generative organs open into the same integumentary ring as the anal orifice; the dental formula is $i. \frac{2}{2}, c. \frac{1}{0}, p. \frac{1}{1}, m. \frac{3}{3}$. (ii.) *Nectogale*, very similar in appearance to the foregoing genus, the "feathering" of the feet and tail being more developed; in colour about like a mole, whitish below.

Erinaceidae.—The Hedgehogs and Gymnuras, or Rat-Shrews, forming the family *Erinaceidae*, differ from the shrews in having a broader tympanic ring, a complete zygomatic arch, and the presence of a short public symphysis; the family is, at the present day, exclusively confined to the Old World. The typical subfamily, the *Erinaceinae*, or hedgehogs, is easily recognized by the spiny nature of the coat, the rudimentary tail, broad pelvis, and the presence of palatal vacuities; the members of this group are distributed over Europe, Africa and a large part of Asia. Dentition $i. \frac{2}{2}, c. \frac{1}{0}, p. \frac{2}{2}, m. \frac{3}{3}$. The Hedgehogs are divided into five genera:—(i.) *Erinaceus*, containing the common European species and about 12 other forms from Europe, Asia and the Canary Islands, ranging from Spain to China. In this genus the pterygoids and bullae are normal, the spines on the crown divided into two groups by a median parting which is narrow and inconspicuous, a hallux is present, and the third incisor normally one-rooted. (ii.) *Aethechimus*, found in Africa and Southern Europe, has the coronal parting broad and the third incisor two-rooted. Some of the forms (4 or 5 in number) are smaller and darker than in *Erinaceus*, *Aethechimus frontalis*, from South Africa, being dark blackish-brown above, and usually black below. (iii.) *Atelerix*, from Northern and East Africa, differs from the above mentioned genera in the hallux being absent; these hedgehogs are small in size and light buff or brownish in colour. *A. albiventris*, from the Sudan, is a very pale coloured species, while *A. spinifex*, from Nigeria, is a brown form. (iv.) *Hemiechimus*, a genus containing a number of forms from the Southern and Eastern Palaearctic Region; some species occur in Egypt and Northern India. In these hedgehogs there is a median parting on the crown. *H. collaris* is a black form from India; another Indian species is the Long-Eared Hedgehog, *H. megalotis*. Lastly, in (v.) *Paraechimus*, the pterygoids are inflated, and a coronal parting is present; found in South Eastern Europe, and from Egypt to India. *P. amir* is a large black coloured species (head and body 240 mm.), and *P. dorsalis* from Arabia has the prickles on the back bright buff coloured with a dark brown dorsal marking.

The Second Subfamily.—The second subfamily *Gymnurinae*, is distinguished by the absence of spines and palatal cavities, the long tail, and narrow pelvis. The species of the typical genus, *Gymnura*, inhabit Tenasserim, the Malay Peninsula, Sumatra, Borneo and a few adjacent islands. *G. gymnura* has the hinder part of the body and limbs black, and the head, shoulders and median part of the anterior back white. *G. rafflesii*, or *alba* is entirely white or pale buff. These Rat Shrews are of considerable size (head and body about 420 mm.). Dentition $i. \frac{2}{2}, c. \frac{1}{0}, p. \frac{1}{1}, m. \frac{3}{3}$. The Lesser Rat Shrews, of the genus *Hylomys*, are easily distinguished by their much smaller size, very short tail (head and body 140 mm.; tail 23 mm.), and dark vole-like coloration. Four races have been described from Borneo, Annam, Siam, Sumatra and Tonking. A closely allied genus is the Sze-Chuan and Yunnan *Neotetracus* in which the tail is of considerable length and the feet large (head and body 120 mm.; tail 63 mm.; hind-foot 26.5 mm.). In the Philippines the group is represented by *Podogymnura truei*, in which the hindfoot is greatly elongated.

The Potamogalidae.—The next family, the *Potamogalidae*, is represented by a single species, *Potamogale velox*, the Otter Shrew, an aquatic insectivore confined to the rivers of the Cameroons, Gaboon and Congo. In this genus the zygomatic arch is wanting; the animal measures about two feet in total length, the laterally compressed tail occupies about half this length. Dentition $i. \frac{2}{2}, c. \frac{1}{0}, p. \frac{2}{2}, m. \frac{3}{3}$.

Family *Centetidae* agrees with the *Potamogalidae* in the absence of zygomatic arch, but the upper molars have narrower crowns. Teats are present on both the breast and abdomen, and some forms are as spiny as hedgehogs; the group is confined to Madagascar. The subfamilies and genera are as follows:—*Centetinae* (i.) *Centetes*, the Tenrec, (*C. ecaudatus*), a large, tailless animal, with harsh, spiny hair; the young ones are striped. Dentition $i. \frac{2}{2}, c. \frac{1}{0}, p. \frac{2}{2}, m. \frac{3}{3}$. (ii.) *Hemicentetes*, the Lesser Tenrec, smaller than the Tenrec, and more spiny; striped throughout life. Dentition $i. \frac{2}{2}, c. \frac{1}{0}, p. \frac{2}{2}, m. \frac{3}{3}$. (iii.) *Ericulus*, the Hedgehog Tenrecs (*E. nigrescens* and *E. setosus*), Hedgehog-like animals having the whole dorsal surface covered with spines. Dentition $i. \frac{2}{2}, c. \frac{1}{0}, p. \frac{2}{2}, m. \frac{3}{3}$. (iv.) *Oryzorictinae*. (i.) *Microgale*, small shrew-like species with long tails (head and body 60 mm.; tail 140 mm.). Dentition, $i. \frac{2}{2}, c. \frac{1}{0}, p. \frac{2}{2}, m. \frac{3}{3}$. (ii.) *Nesogale*, larger than *Microgale* but with a proportionately shorter tail. (iii.) *Oryzorictes*, distinguished by its shorter tail (47 mm.); the species are fossorial. (iv.) *Limnogale*, a large aquatic form (*L. mergulus*) with webbed toes and a long laterally compressed tail (head and body 150 mm., tail 140 mm., hind-foot 15 mm.).

Closely allied to the *Centetidae* is the family *Solenodontidae*, which contains but a single genus, *Solenodon*, and two species *S. paradoxus* and *S. cubanus*, the former from Hayti, and the latter from Cuba. The family is distinguished by the skull being constricted behind the orbits, the descent of the testes into the perineum, and in having the teats postinguinal. *Solenodons*, which look like huge rats, have the same dental formula as *Microgale*; they have long snouts and tails, and their bodies are clothed with long, coarse hair. The tail is naked, the whiskers very long, and the ears large.

The Chrysochloridae.—The last family of Insectivora is the *Chrysochloridae* or Golden Moles. The skull is conical and not constricted between the orbits; zygomatic arch and auditory bullae well developed, post orbital process absent. Upper molars tribuccular, with very tall crowns. The ears are small and the eyes concealed beneath the skin; the teats are both pectoral and inguinal. The forefeet are specialized for burrowing, the two middle claws of the manus being very powerful. All the species are fossorial and confined to south, east and central Africa. They are usually some shade of brown or grey with a brilliant metallic lustre, varying from peacock-green to golden bronze. Four genera are recognized:—(i.) *Bematis*, the Giant Golden Mole of Pondoland and the Transvaal. (ii.) *Chrysospalax*, the Natal Golden Moles, rather smaller than *Bematis*. (iii.) *Amblysomus*, the Golden Moles of South-east and Central Africa; smaller than the foregoing genera (head and body 115 mm.; tail 13 mm.), usually sepia brown or chocolate with bronze or pinkish metallic lustre. Teeth only 36 in number owing to the absence of the last pair of molars. (iv.) *Chrysochloris*, the typical genus, with 40 teeth, from South and Central Africa; about equal in size to *Amblysomus*; *C. asiatica*, from Cape Town, is a grey animal with a bluish sheen, while *C. congicus*, has a white face.

INSECTIVOROUS PLANTS. Insectivorous or, as they are sometimes more correctly termed, carnivorous plants are, like the parasites, the climbers or the succulents, a physiological assemblage belonging to a number of distinct natural orders. They agree in the extraordinary habit of adding to the supplies of nitrogenous material, afforded them in common with other plants by the soil and atmosphere, by the capture and consumption of insects and other small animals. The curious and varied mechanical arrangements by which these supplies of animal food are obtained and utilized are described under the headings of the more important plants.

The best known and most important family of insectivorous plants—*Droseraceae*—includes six genera: *Byblis*, *Roridula*, *Drosera*, *Drosophyllum*, *Aldrovanda* and *Dionaea*, of which the last three are monotypic, i.e., include only one species. The *Sarracenaceae* contain the genera *Sarracenia*, *Darlingtonia*, *Heliamphora*, while the true pitcher plants or *Nepenthaceae* consist of the single large genus *Nepenthes*. These three families are closely allied and form the series *Sarraceniales* of the free-petalled

INSECTIVOROUS PLANTS

Certain plants, as sundews, butterworts, bladderworts and pitcher-plants, supplement their food supply by capturing and consuming insects and other small animals, being provided with special structures (Trumpets (*Sarracenia flava*); 1A. Pitcher-like leaves. 2. California Pitcher-plant (*Drosera rotundifolia*); 2A. Young pitchers. 3. Northern Pitcher-plant (*Sarracenia purpurea*);

3A. Pitcher-like leaves. 4. Parrot-headed Pitcher-plant (*Sarracenia psittacina*); 4A. Pitcher-like leaves. 5. Red Trumpet-leaf (*Sarracenia rubra*); 5A. Leaves of the plant. 6. Venus's Fly-trap (*Dionaea muscipula*); 6A. Fly-catching leaves.

7. Sundew (*Drosera intermedia*). 8. Mindoroan Pitcher-plant (*Nepenthes Burkei*). Philippine Is.; 8A. Leaf pitchers. 9. Yellow Butterwort (*Pinguicula lutea*); 9A. Viscid leaves

INSECTIVOROUS PLANTS

PLATE

section (Choripetalae) of Dicotyledons. The curious pitcher-plant, *Cephalotus follicularis*, comprises a separate family. Cephalotaceae, closely allied to the Saxifragaceae. Finally the genera *Pinguicula*, *Utricularia*, *Genlisea* and *Polypompholix* belong to the gamopetalous family Lentibulariaceae.

While the large genus *Drosera* has an all but world-wide distribution, its congeners are restricted to well-defined and usually comparatively small areas. Thus *Drosophyllum* occurs only in Portugal and Morocco, *Byblis* in tropical Australia, and, although *Aldrovanda* is found in Queensland, in Bengal and in Europe, a wide distribution explained by its aquatic habit, *Dionaea* is restricted to a few localities in North and South Carolina. *Cephalotus* occurs only near Albany in Western Australia, *Heliamphora* on the Roraima Mountains in Venezuela, *Darlingtonia* on the Sierra Nevada of California, and these three genera too are as yet monotypic; of *Sarracenia*, however, there are seven known species scattered over eastern North America but mostly in the south-eastern United States. The 60 species of *Nepenthes* are mostly natives of the hotter parts of the Indian Archipelago, but a few range into Ceylon, Bengal, Cochin China, and some even occur in tropical Australia on the one hand, and in the Seychelles and Madagascar on the other. *Pinguicula* is abundant in the north temperate zone, and ranges down the Andes as far as Patagonia; the 210 species of *Utricularia* are mostly aquatic, and some are found in all save polar regions; their unimportant congeners, *Genlisea* and *Polypompholix*, occur in tropical America and south-western Australia respectively. It is remarkable that all the insectivorous plants agree in inhabiting damp heaths, bogs, marshes and similar situations where water is abundant, but where they are not brought into contact with the plenteous supply of inorganic food as are the roots of most terrestrial plants.

INSECT PESTS: see ENTOMOLOGY, *Economic*.

INSECTS, the ordinary name used for those animals placed by zoologists in the class Insecta (or Hexapoda) of the phylum ARTHROPODA (*q.v.*) and whose scientific study forms that branch of zoology termed ENTOMOLOGY (*q.v.*). In former times the word insect had a much wider and looser significance than to-day and the class Insecta of Linnaeus (1735) included those animals which form the whole of the Arthropoda of modern zoologists. Linnaeus's term Insecta was first used in a restricted sense by M. J. Brisson (1756), whose application of the word has since been generally adopted. In 1825 P. A. Latreille applied the term Hexapoda to the insects and, since it expresses a very characteristic feature of those animals, it is employed by some authorities.

A true insect has its body divided into three distinct regions—head, thorax and abdomen—each composed of a definite number of segments (fig. 1). The head bears a single pair of feelers or antennae, a pair of mandibles and two pairs of accessory jaws or maxillae. The thorax carries three pairs of legs (hence the term Hexapoda) and usually two pairs, more rarely one pair, of wings. The abdomen is devoid of walking limbs and the genital opening is situated near the anal extremity of the body. Respiration takes place by means of internal air-tubes or tracheae which communicate with the exterior by a variable number of paired openings or spiracles. After hatching from the egg the further development is rarely direct and a metamorphosis is usually undergone.

Insects probably outnumber in species all the rest of the animal kingdom, and their great numerical predominance is to be ascribed to their extraordinary adaptability to live under the most diverse conditions, and to the possession of wings. Insects represent the highest grade of evolution among invertebrate animals not only as regards complexity of structure, but also in psychic development as expressed in instinct. They have a world-wide range, species even occurring in the polar regions, on snow-clad mountains and glaciers, in all types of fresh water and in salt lakes; a few have invaded the sea while others have established themselves in hot springs, in deep wells and in caves where light never penetrates. It is, however, in the Tropics that insect life exhibits its greatest wealth of species and diversity of form and coloration.

In point of size insects present a wide range of differences: as J. W. Folsom has well expressed it, some insects are smaller than

the largest Protozoa and others are larger than the smallest Vertebrata. If size be gauged by bulk combined with body-length, the beetle *Macrodonia cervicornis*, which ranges up to 150mm. (6in.) long, is to be regarded as one of the giants, while a length of 33cm. (13in.) is reached by some of the greatly attenuated stick-insects

FROM IMMS, "GENERAL TEXT BOOK OF ENTOMOLOGY" (METHUEN & CO.)

FIG. 1.—DIAGRAM SHOWING THE STRUCTURE OF A PRIMITIVE WINGED INSECT

(*q.v.*). In wing expanse alone the moth *Erebus agrippina* with a spread of 280mm. (11in.) is unsurpassed among living insects although certain fossil dragon-flies measure over 2ft. from wing to wing. At the other end of the scale there are beetles which do

FIG. 2.—SCHEMATIC VIEW TAKEN ACROSS THE THORAX OF WOOD WASP

not exceed a length of $\frac{1}{4}$ mm. and some minute wasp-like parasites are even smaller.

Apart from the interest that the structure habits and transformations of insects afford to the nature student the whole class is of very great importance in its relations to man. Many species are a direct menace to his food supply, some attack raw materials and others act as vectors of the pathogenic agents of disease both

in man and in domestic animals. (See ENTOMOLOGY: *Economic and Medical*.)

EXTERNAL ANATOMY

Skeleton and Segmentation.—The skeleton of an insect is the hard part which resists decay after death and forms the dried specimens kept in collections, and also those parts of insects found as fossils. The skeleton is mainly external and is the hard-

MIAL & DENNY, "THE COCKROACH" (LOVELL, REEVE & CO.), BY COURTESY OF DR. STEPHEN MIAL

FIG. 3.—FRONT VIEW OF HEAD OF COCKROACH

ened cuticle or outermost layer of the integument or body-wall. It is composed of a substance termed chitin and is produced by the hypodermis or cellular layer of the integument. The skeleton remains membranous and unchitinized at the joints or other places where movement occurs, but over the rest of the body it is composed of separate areas or sclerites which meet along definite lines or sutures: in cases where adjacent sclerites are fused the sutures are obliterated. Like other Arthropods, insects are seg-

FIG. 4.—UNDER SURFACES OF HEADS OF TWO MEMBERS OF BEETLE FAMILY. ABOVE, WEEVIL; BELOW, GROUND BEETLE

mented animals and a segment consists normally of a dorsal region or tergum, a lateral region or pleuron on each side, and a ventral region or sternum—each region being composed of one or more sclerites. Typically, a segment bears a pair of jointed appendages or limbs attached on either side between the sternum and the pleuron (fig. 2); these appendages are modified according to the various functions they perform and are absent from most of the abdominal segments. In addition to forming the skeletal covering, the integument also produces the hairs, scales, spines and other external structures.

Colouration.—Many of the colours of insects are due to pigments which occur in the cuticle, or below the cuticle in the hypodermis, or in the blood. Pigmentary colours are mostly reds, yellows, browns and blacks, but very rarely blues, and are produced as the result of chemical changes that go on in the body of the insect. The experiments of F. Merrifield and others have shown that they are often greatly influenced by heat or cold and

FIG. 5.—TYPES OF ANTENNAE

other means. Some pigments are excretory products and, in the cabbage white butterflies, the white scale colour is due to uric acid and certain yellows, reds and possibly greens, of other butterflies and moths and derivatives of this same substance. The yellows, greens and reds of many caterpillars are derived from the chlorophyll of the food, which enters the blood and the coloration is due to their visibility through the integument. Certain blacks and browns are of the nature of melanins and are induced by an oxidase. It is noteworthy that the pigments of many butterflies and moths are brilliantly fluorescent when subjected to ultra-violet light in a completely darkened room.

Other colours are the result of structural features that bring about interference; in a number of cases fine parallel ridges or striae on the scales produce iridescent colours. In some instances, as in Lycaenid or blue butterflies, little or no pigment may be present, while the metallic greens, blues and coppers of other insects are produced by scale-structure in combination with a backing of pigment. Very often this pigment is black, but the emerald green of an Ornithoptera butterfly has been shown to be due to scale structure combined with yellow pigment in the

walls of the scales. The golden iridescence of *Cassida* beetles is produced by a film of moisture beneath the surface cuticle and is quickly lost after death.

Head.—The head (figs. 3 and 4) is composed of six segments which are so intimately fused together that evidence of its segmental structure is chiefly derived from the presence of appendages. On the upper surface of the head of a cockroach or other generalized insect a Y-shaped *epicranial suture* is present, the sclerite between the arms of the Y being the *frons*, while behind the frons the rest of the head is termed the *epicranium*. Anterior to the frons is the *clypeus*, which is often fused with it, and in front of the clypeus is a movable upper lip or *labrum*; the inner sensory lining of the labrum is termed the *epipharynx*, which, along with the labrum, is often greatly developed in sucking insects. Paired compound eyes are almost always present on the epicranium and below the eyes are the *genae* or cheeks: three simple eyes or *ocelli* are also frequently evident. The head is attached to the thorax by a neck and the region of attachment is indicated by the large *occipital foramen*: on the floor of the head in front of this foramen there is sometimes present a median chin sclerite or *gula* (fig. 4). The head bears four pairs of appendages—antennae, mandibles, first maxillae and second maxillae. The *antennae* or feelers are composed of a variable number of joints or segments and are very diverse in form: they bear sense organs

the *mentum* and the latter carries the *pre-mentum* which shows indications of a paired structure. The pre-mentum when completely developed carries paired lobes on either side; these lobes are the *paraglossae* and *glossae* which are homologous with the galeae and laciniae of the first maxillae. Collectively they form the *ligula*, but often one or both pairs of these lobes are wanting or fused. Jointed *labial palpi* arise on either side from the

outer border of the pre-mentum. On the floor of the mouth-cavity, above the base of the labium, is the tongue or hypopharynx, which receives the opening of the salivary duct; in the more primitive insects and some larvae, paired lobes—the *superlinguae* (*maxillulae*)—are present in relation with the hypopharynx.

The mouth parts of insects present many modifications of form in accordance with the uses to which they are subjected. Thus, in insects which feed by sucking, the galeae of the maxillae are prolonged into a proboscis, and in piercing insects the mandibles, maxillae and other organs are developed into needle-like stylets. These and other modifications are dealt with under the separate groups concerned.

Thorax.—Three segments make up the thorax which is the locomotory centre of the body: they are termed the *prothorax*,

FROM SNODGRASS, "ANATOMY AND PHYSIOLOGY OF THE HONEY BEE" (U.S. DEPT. OF AGRICULTURE)

FIG. 7.—TERGUM OF THE MESO-THORAX OF CRANE-FLY

FIG. 6.—PRINCIPAL MOUTH PARTS OF A COCKROACH

of smell and touch and are often more conspicuously developed in the male than in the female (fig. 5). The *mandibles* (figs. 3 and 6) are the principal jaws and are used for seizing and crushing the food. The first maxillae are accessory jaws; each maxilla consists of two basal pieces, *cardo* and *stipes*, the latter bearing an outer lobe or *galea* and an inner toothed lobe or *lacinia*. Externally the maxilla carries a jointed *maxillary palp* which bears organs of special sense. The second maxillae form the lower lip or *labium* and are composed of a pair of partially fused appendages. Its large basal plate or *sub-mentum* is joined in front with

FIG. 8.—DIAGRAMMATIC VIEW OF THORAX OF WOOD WASP

mesothorax and *metathorax*. The tergum of the prothorax is formed by the pronotum, and although large in cockroaches, plant bugs and beetles is usually reduced in other winged insects. In the mesothorax and metathorax the tergum is made up of a

FIG. 9.—SIDE VIEW OF A TYPICAL LEG OF AN INSECT

series of sclerites, one behind the other; viz., *prescutum*, *scutum*, *scutellum* and *post-scutellum* (fig. 7)—of these the scutellum of the mesothorax is often especially prominent. Laterally each pleuron is composed of an anterior sclerite or *episternum* and a posterior sclerite of *epimeron* (fig. 8). On the ventral side, each sternum is composed of variable numbers of sclerites in different groups.

Legs.—A pair of legs is borne on each thoracic segment. A leg is formed of five parts (fig. 9); viz., a broad subglobular *coxa*

which articulates with the thorax; a small *trochanter*; a stout elongate *femur*; a slender *tibia*; and a *tarsus* consisting typically of five segments or joints. The last tarsal segment bears a pair of claws, more rarely a single claw, and beneath the claws there is a pair of adhesive pads or *pulvilli* which aid in walking over steep or smooth surfaces. Legs vary greatly in form according to whether they are used for running, burrowing, grasping, etc.

Locomotion.—While walking an insect usually moves its legs in such a way that the fore and hind legs of one side, and the middle leg of the other side, progress forward almost at the same moment, the body being supported, as it were, on a tripod formed by the remaining three legs. The anterior leg pulls the body forward and the hind leg chiefly pushes in the same direction, while the middle leg steadies the body and helps to raise or lower it.

Wings.—Wings are lateral outgrowths of the integument of the tergum of the meso- and metathorax and commence to develop in the larva or nymph as the case may be. They exhibit great variety of form and structure in different groups of insects and may be wanting altogether: some insects, such as bristle-tails and spring-tails, have never acquired wings, while others such as lice, fleas, worker ants, etc., although wingless, are believed to have been derived from winged ancestors. A wing is composed of an upper and a lower membrane and between these two layers it is strengthened by a framework of chitinous tubes known as veins. The latter develop very largely in relation with the air-tubes or tracheae which enter the developing wing when it is little more than a bud-like outgrowth. The venation, or ar-

FIG. 10.—HYPOTHETICAL TYPE OF WING VENATION

range of the wing-veins, is of great importance in classification and the homologies of the veins are largely determined by studying the wings of fossil insects, and the pre-existing tracheae in the wing-buds of the nymphs and pupae of living insects; in the more primitive insects each principal vein is preceded by the trachea from which it takes its name.

The wing-vein nomenclature largely used to-day is known as the Comstock-Needham system. It is based upon the conclusion that all orders of winged insects have a venation derived from a common primitive type and that there are eight principal veins. These veins and their recognized symbols are shown in fig. 10. The actual venation, it must be understood, departs by a greater or lesser degree from this primitive plan and either reduction or multiplication of the veins and their branches is the rule. Between the veins are cross-veins which divide the wing into closed areas or cells, each cell taking its name from the vein which

forms its anterior boundary.

Flight.—During flight the wings of an insect have an up-and-down motion combined with movement in the backward and forward directions. This results in the path or trajectory made by the apex of the wing taking the form of a continuous series of double loops resembling the figure 8. These movements are effected by two sets of muscles—indirect muscles and direct mus-

BY COURTESY OF UNITED STATES DEPARTMENT OF AGRICULTURE

FIG. 11.—ACTION OF THE INDIRECT WING MUSCLES DURING FLIGHT (fig. 11). The indirect muscles are the largest in the body and are attached to the thorax and not to the wing-bases. They consist of two groups of muscles: (1) a pair of dorso-ventral muscles, by whose contraction the dorsal wall of the thorax is depressed, with the result that the wings are forced upward, owing to the peculiar nature of their articulation with the thorax; (2) a pair of longitudinal muscles, by whose contraction the dorsal wall of the thorax becomes arched upwards, and the wings consequently forced downwards. The rapid alternate contraction of these two groups of muscles, therefore, raises and lowers the wings by their action upon the dorsal wall of the thorax. The direct muscles arise in the thorax but are inserted on the bases of the wings: they are smaller and more numerous than the indirect muscles, and in the blow-fly they amount to ten pairs; they function in turning the wings backwards and forwards in a horizontal direction as well as aiding in steering. In most insects the important flight muscles are the indirect muscles, but in dragon-flies the chief muscles are inserted directly on to the bases of the wings.

The wings are capable of very rapid motion: it has been found that the house-fly makes 330 strokes per second, a bee 190, a dragon-fly 28 and a butterfly nine strokes per second. This has been determined by using captive insects in such a manner that the tip of the wing comes in contact with a revolving drum covered with smoked paper. The least contact of the wing removes a minute area of the coating and exposes the white paper beneath. Comparison of such a record with one made in a similar manner by means of a tuning fork, of an ascertained frequency of vibration, enables the rapidity of wing movement to be accurately determined.

Abdomen.—The abdomen (fig. 12) is usually composed of ten segments, but since modification has taken place both anteriorly and posteriorly, it is often difficult to determine their limits in these two regions. Vestiges of an 11th segment are present in a few orders and in the Protura there are 12 segments: in all cases the anus is placed on the last segment. The latter region in generalized insects also frequently bears a pair of jointed tail-feelers or *cerci*, as in bristle-tails and may-flies, while the eighth and ninth segments carry ventral appendages known as *gonopophyses*. In the female they form two pairs of valves borne on the ninth

FIG. 12.—MALE AND A FEMALE COCKROACH

segment and enclosed in a pair of broader blades borne on the eighth segment, the whole forming an egg-laying organ or *ovipositor* (fig. 13). This structure is adapted to perform different uses in different groups of insects; in bees, wasps and many ants it is modified to form a sting: in saw-flies it is used for sawing niches in plant tissues for placing the eggs: in wood-wasps it drills holes for placing the eggs deep in wood, while in many ichneumon flies and their allies it is used for piercing other insects

FIG. 13.—APEX OF ABDOMEN WITH OVIPOSITOR OF GRASSHOPPER

in whose bodies the eggs are laid. In some insects there is no ovipositor, while in many beetles and flies the terminal segments of the body are developed in a telescopic manner, thus functioning as an egg-laying organ. In male insects the gonopophyses function as external organs of reproduction; they comprise a pair of small valves or *parameres* associated with the intro-mittent organ, and a pair of large valves or claspers used for grasping the female—both pairs of organs belonging to the ninth segment.

INTERNAL ANATOMY

The internal organs of an insect, like those of other Arthropods, lie in a common body-cavity or haemocoel which contains blood and is in free communication with and forms part of the general circulatory system.

Nervous System and Sense Organs.—The central nervous system consists typically of a ventral nerve cord with a pair of nerve centres or ganglia in each segment of the body: it is joined by a connective on either side of the gullet with the brain (fig. 14). The brain lies in the head just above the gullet and consists of three fused ganglia which innervate the antennae and visual organs. The first ganglion of the ventral cord is the suboesophageal ganglion which lies in the head just below the gullet and innervates the mouth-parts. The next three ganglia are situated one in each of the thoracic segments and innervate the wings and legs, while the remaining ganglia of the ventral cord belong to the abdomen. In the more specialized insects a variable number of the ganglia undergo fusion and as in the house-fly, all the thoracic and abdominal ganglia are merged into a common centre.

Connected with the nervous system are the organs of special sense. Visual organs consist of compound eyes and ocelli: typ-

FIG. 14.—NERVOUS SYSTEM OF AN EARWIG

FIG. 15.—SECTION THROUGH THE EYE AND OPTIC LOBE OF BRAIN OF WORKER HIVE BEE

vided cornea is replaced by a single biconvex lens which overlies the visual elements (fig. 16). Vision by means of compound eyes is explained by the mosaic theory which maintains that only those rays of light entering a facet which are parallel with the long axes of the ommatidia, reach the retina where they register a minute part of the whole field of vision, oblique rays being absorbed by the surrounding pigment. The entire image will consequently be a mosaic made up of as many units as there are

FIG. 16.—SECTION THROUGH AN OCELLUS OF A CUCKOO SPIT INSECT

facets to the cornea. The compound eye appears to be an organ especially adapted for perceiving moving objects quickly, while the ocelli distinguish very near objects and varying intensities of light. Auditory organs in their simplest form consist of fine rods suspended between two points of the integument and connected with nerve-fibres: in such a condition they are present in many insects and larvae. In other cases more elaborate organs are developed, and in grasshoppers (*Acridiidae*) there is a tympanic membrane on either side of the first abdominal segment which is in contact with a delicate sac containing fluid and receiving

nerve-endings (fig. 17). In long-horned grasshoppers and crickets a small swelling below the knee joint bears two narrow slits which lead into chambers whose delicate walls are in contact with air-tubes and bear nerve-endings. In both these examples sound waves impinge on an auditory membrane whose vibrations are transmitted by nerve fibres to the central nervous system. Sense perception of other kinds takes place by means of modified hairs

FIG. 17.—LATERAL VIEW OF A LOCUST

covered by a very delicate cuticle and in direct connection with a nerve fibre. Included in this category are tactile organs which closely resemble ordinary hairs and are widely distributed over

FIG. 18.—SENSE ORGANS FROM ANTENNA OF THE HORNET

the body and appendages: olfactory organs (fig. 18) which are more variable and modified in form and are present in large numbers on the antennae, especially of male insects: and gustatory organs whose taste function is presumed from their location on parts near or connected with the mouth-cavity.

Muscular System (fig. 19).—Unlike those of vertebrates the

voluntary and involuntary muscles of insects are cross-striated. In the thorax and abdomen the muscles are arranged in (1) a longitudinal series, both tergal and sternal muscles being present, (2) a dorso-ventral series and (3) a pleural series. In the thorax there are also other special muscles connected with the movements of the legs and wings. The head contains numerous muscles which comprise the abductor and adductor muscles of the mouth-parts and cervical muscles controlling the movements of the head.

Respiratory System.—The respiratory organs consist of a much branched system of air-tubes or *tracheae* (fig. 21), which are kept distended by spirally arranged thickenings of their chitinous lining (fig. 20). The small tracheae end in fine capillaries or *tracheoles* which pass to the various organs of the body. Air enters the tracheae through paired lateral openings or *spiracles*: each spiracle is surrounded by a chitinous rim and is generally provided with a closing apparatus and often special devices to exclude foreign matter. The typical number of spiracles is ten pairs—two pairs on the thorax and eight pairs on the abdomen, but this number is often

MIALL AND DENNY, "THE COCKROACH" (LOVELL REEVE & CO.) BY COURTESY OF DR. S. MIALL

FIG. 19.—VENTRAL MUSCLES AND NERVE CORD OF THE COCKROACH

Respiratory movements on the part of the insect facilitate the entry of air into the tracheae whence it passes by diffusion into the tracheoles, where it finally gives up its oxygen to the tissues. Carbon dioxide is got rid of partly by diffusion through membranous areas of the integument and partly by passage through the tracheae, it being finally expelled through the spiracles by the contraction of the tergosternal muscles which compress the body. Many aquatic insects breathe by means of tracheal gills. In other insects, which have no tracheae, respiration is cutaneous.

Circulatory System.—The heart in an insect is represented by a tubular contractile dorsal vessel which is composed of successive chambers and runs along the middle line of the back, just below the integument (fig. 1). It lies in the pericardial sinus

FIG. 20.—PORTION OF A TRACHEAL TUBE AND BRANCHES

whose floor is formed by the pericardial diaphragm, and there is usually a ventral diaphragm, enclosing a peri-neural sinus surrounding the nerve cord (fig. 8). The dorsal vessel pumps the blood forward, through its anterior prolongation or aorta, into the body-cavity: here it bathes the various organs and flows through the appendages. The pulsations of the two diaphragms keep the blood in circulation and it is eventually returned to the pericardial sinus through openings in the diaphragm. Here it makes its way back to the dorsal vessel, entering the latter organ through paired valvular inlets placed at the constrictions between

adjacent chambers. The blood is composed of a fluid or plasma containing amoeba-like corpuscles, somewhat resembling the leucocytes of mammalian blood. Although it plays a part in respiration, its chief function is the circulation of nutrient material among the various organs of the body.

Digestive System.—The digestive canal (fig. 22) is divided into fore-gut, mid-gut or stomach and hind-gut: the first and

MIALL AND DENNY, "THE COCKROACH" (LOVELL REEVE & CO.) BY COURTESY OF DR. S. MIALL

FIG. 21.—VENTRAL PORTION OF AIR TUBES IN A COCKROACH

third regions are formed as tubular inpushings of the integument and are lined with thin cuticle, while the mid-gut is developed as a separate chamber. The fore-gut consists of a narrow gullet, a sac-like crop and often a gizzard: in Lepidoptera and many flies the crop is a separate food-reservoir connected by a canal with the gullet (fig. 23). On either side of the fore-gut are the salivary glands which open into the mouth-cavity. The mid-gut is short, and often provided with outgrowths or caeca, while the hind-gut consists of a tubular intestine and an end-chamber or rectum. Arising from the hind-gut, near its junction with the mid-gut is a variable number of slender Malpighian tubes. The food during mastication is mixed with saliva whose enzymes act upon the starchy matter. The secretions of the mid-gut deal chiefly with proteids and fats and resemble those of the pancreas of vertebrates. Digestion often takes place largely in the crop while the mid-gut is the seat of absorption and the hind-gut conducts waste products to the exterior.

Excretory System.—The Malpighian tubes function as kidneys and eliminate urates and other waste products from the blood, discharging them into the hind intestine (figs. 22 and 23). In many insects the fat-body, or irregular tissue found in the body-cavity, also functions in an excretory capacity, but it mainly stores up nutrient reserves to be drawn upon during metamorphosis.

Reproductive System.—In the female (fig. 24) the ovaries are paired organs each formed of a variable number of egg-tubes or ovarioles which contain the developing ova. The latter as they ripen pass down the oviducts to enter a median passage or vagina and are discharged through the female genital pore which is usually placed between the sterna of the eighth and ninth abdominal segments. There are also generally a *spermatheca* for storing the sperms and paired accessory glands. In the male (fig. 24) the testes are likewise paired and are formed of seminal tubes which produce the sperms. The sperms are discharged into paired ducts or *vasa deferentia*, and finally into a median ejaculatory duct opening in the *aedeagus* or intromittent organ, which is placed between the ninth and tenth abdominal sterna. Sometimes the *vasa deferentia* are locally enlarged as seminal vesicles for storing the sperms and accessory glands may also be present. Fertilization of the ova depends upon the union of the sexes, which, in some insects, may occur several times in the life of the individual, either male or female.

EMBRYOLOGY

The Egg.—The eggs are usually rich in yolk for nourishing the growing embryos: many eggs are elongate-oval in shape, others are spherical, and some are flattened or flask-shaped: the outer coat (*chorion*) is often elaborately sculptured. Eggs may be laid

singly or in groups: enclosed in capsules or *oothecae*, as in cockroaches, etc., or enveloped in a gelatinous mucilage as in some midges and caddis flies, which lay them in water.

Early Development.—After maturation and fertilization of

MIALL AND DENNY, "THE COCKROACH" (LOVELL REEVE & CO.) BY COURTESY OF DR. S. MIALL

FIG. 22.—FOOD CANAL OF A COCKROACH

the egg have taken place, development commences by the division of the segmentation nucleus which results in the formation of a number of cleavage nuclei. These pass to the periphery of the egg where they arrange themselves in a single layer or *blastoderm* (fig. 25) which encloses the yolk. In many insects a group of cells appears at the hind pole of the egg: these cells are derived from the segmentation nucleus but take no part in blastoderm formation, and are the primitive germ cells (figs. 25 and 26) which ultimately give rise to the future ova or spermatozoa as the case may be. At a later stage they become enclosed in the mesoderm which forms the sexual organs. Early in development the blastoderm becomes thickened on the future ventral surface forming the germ band or ventral plate (fig. 25). Along this band a pair of longitudinal folds arise which grow and meet, thus converting the one-layered rudiment into two layers—the outer layer being the ectoderm and the inner layer the mesoderm (fig. 26). This stage, known as the *gastrula*, which is an important phase in the development of all animals, is subject to several variations in insects.

Formation of the Embryo (fig. 27).—Early on, the germ band becomes divided by transverse furrows into a series of seg-

FROM IMMS' "GENERAL TEXTBOOK OF ENTOMOLOGY," AFTER LOWNE

FIG. 23.—DIGESTIVE CANAL OF A MUSCID FLY

ments of which six form the future head, three form the thorax and 11 or 12 form the abdomen: at this stage the germ band may be referred to as the embryo. On each segment, except the first and last, pairs of bud-like appendages appear. These, in all insects, form the future antennae, mouth-parts and legs, while the remain-

der, with certain exceptions, usually disappear before the embryo is fully developed. The transient appendages are the small second pair, behind the antennae, and those borne on the abdomen. Among Apterygota certain of the abdominal appendages form those of the adult and in caterpillars they develop into abdominal feet. In other insects cerci, when present, are formed from the last pair, but the rest of the abdominal appendages disappear. The

FIG. 24.—REPRODUCTIVE ORGANS OF WINGED TERMITE

gonapophyses are believed to be derived from abdominal appendages of the eighth and ninth segments, but direct proof is wanting. Along either side of the middle line of the ectoderm a pair of ridges develop which are the fundamentals of the nervous system. They become segmented into paired swellings or *neuromeres*, one neuromere lying in each embryonic segment. The first three neuromeres give rise to the brain, the next three form the sub-oesophageal ganglion and the remainder form the ganglia of the thorax and abdomen. At a later stage pits appear on the outer side of the last two thoracic and the first eight or nine abdominal appendages, these being the rudiments of the spiracles.

Embryonic Membranes (fig. 28).—In some insects such as beetles the embryo remains at the surface of the yolk, but it subsequently becomes covered by folds which arise along its edges. These folds grow towards one another and fuse, and in this way enclose the embryo in an amniotic cavity which is covered by an outer membrane or *serosa* and an inner membrane or *amnion* (fig. 28). In some other insects such as butterflies and dragonflies the embryo becomes sunk into the yolk and a portion of the non-embryonic part of the blastoderm becomes necessarily carried in with it, forming the amnion. In a moth or butterfly the embryo sinks into the yolk without change of orientation, but in dragonflies it moves through an arc until its position is completely reversed on the dorsal side of the yolk. Here it rests for a while and again passes through the same arc to its original ventral position.

Digestive System (fig. 29).—In the positions of the future mouth and anus the ectoderm becomes impushed to form the rudiments of the fore-gut and hind-gut respectively. The method of origin of the mid-gut is much disputed: by some embryologists it is believed to arise partly from the mesoderm and partly from cells budded off from the previously mentioned gut-rudiments—others claim its origin from the latter source only. The Malpighian tubes develop as outgrowths from the hind-gut when the latter is little more than a pit, and subsequently become carried inwards as the gut-rudiment deepens.

Dorsal Closure (fig. 30).—As development proceeds the embryo broadens out and gradually grows around the yolk until its sides finally meet and fuse along the dorsal region. In many in-

sects either the amnion or serosa ruptures over the region of the embryo to allow of its growth, but in *Lepidoptera* these membranes remain intact, and the amniotic cavity follows the growth of the embryo around the yolk.

FIG. 25.—STAGES OF DEVELOPMENT IN THE EGGS OF A BEETLE, IN SECTION

Integument and Tracheal System.—When the dorsal closure is completed the embryo is surrounded by ectoderm which forms, in addition to the organs previously mentioned, the whole

FIG. 26.—TRANSVERSE SECTION OF THE EGG OF THE HIVE BEE

integument of the body and its appendages together with the tracheal system and salivary glands. The tracheae arise from the original spiracular pits which deepen into tubes and become freely branched as development proceeds.

Mesoderm and Organs Derived from It (fig. 30).—The

mesoderm or inner layer of the germ band undergoes segmentation corresponding with that of the ectoderm. Coelomic cavities appear in these mesoderm segments, but they subsequently break down and take little part in the formation of the permanent body-cavity as happens in so many animals. The mesoderm gives rise to the dorsal vessel, fat-body, muscles and the sexual organs and their paired ducts, but the vagina and the ejaculatory duct respectively are derived as inpushings of the ectoderm. The body-cavity is chiefly formed from a space that is produced by the separation of the yolk from the mesoderm in the mid-ventral region: this space extends laterally with the upward growth of the embryo till the complete body-cavity is formed.

Later Development and

Eclosion.—Once the fundamentals of the various organs are laid down the final stages of development largely consist in their continued growth and structural differentiation. When fully developed the embryo becomes the young insect and its method of hatching or eclosion from the egg varies in different groups. Some insects (e.g., caterpillars) simply eat their way out through the egg-shell, others rupture it by body movement, or there may be a lid or operculum which is pushed apart from the rest of the shell by the insect in its efforts to emerge. In some plant-bugs and other insects a hatching spine or egg-burster is present on the head and after eclosion is effected this structure is left behind.

FIG. 27.—EMBRYO OF A SILKWORM

REPRODUCTION

Insects exhibit a diversity of reproductive phenomena unparalleled in other animals. Nowhere else do we find parthenogenesis both sporadic and cyclic, viviparity, paedogenesis and polyembryony all within the limits of a single group of the animal kingdom. Normally reproduction is dependent upon the meeting of the sexes which leads to the fertilization of the ova preparatory to egg-laying.

Mating.—In some insects mating takes place only once and death supervenes soon afterwards, as in may-flies. In the hive bee the queen has a life of several years, but a single act of mating is sufficient for fertilizing the eggs during that long period, and the male perishes soon after pairing. In other insects a male may pair freely with several females and in many beetles repeated mating takes place in the life of both sexes. Burgess found that in the ground beetle *Calosoma sycophanta* the female required several matings or a large proportion of the eggs would be infertile.

Oviposition and Fecundity.—Egg-laying or oviposition takes place in various ways as already mentioned and the eggs are deposited in situations expressly adapted for the immediate needs of the future offspring. In some cases the female simply drops the eggs at random while flying low, as happens in certain moths whose larvae feed on grasses or their roots. Very commonly the eggs are laid singly or in masses on the food-plant of the future larvae: or they may be inserted into plant tissues, as in some grasshoppers. When inserted more deeply excrescences or galls may arise as in saw-flies, gall-wasps and gall-midges. Other insects lay their eggs beneath the soil, while parasitic species lay them on or within the bodies of the hosts which support their future offspring.

The number of eggs laid by the female greatly varies among different species. In the Phylloxera of the vine and the woolly aphid, the winter females lay but a single large egg apiece; the

mussel scale in England lays on an average less than 40 eggs; the moth *Hadena oleracea* lays over 800 eggs, and the house-fly may deposit over 2,000 eggs during its life. The maximum fecundity is reached among termites whose queens are often little more than huge inert egg-laying machines producing upwards of 4,000 eggs every 24 hours, and 1,000,000 eggs a year during a life of perhaps six to nine years.

Viviparity.—In some insects embryonic development takes place while the eggs are still within the body of the female and living young are consequently produced. This is a very general phenomenon throughout the summer in all true aphides. Viviparity is also not rare among certain flies and is occasionally found in some beetles. Among flies there are species which produce large numbers of eggs whose larvae are "born" as soon as they issue from the eggs, while there are others such as the tsetse flies and sheep ked, which produce a very small number of eggs and the larvae are retained in the body of the female and nourished till fully grown. They are then "born" and turn to pupae almost immediately afterwards.

Parthenogenesis.—Parthenogenesis, or reproduction without the act of fertilization, exhibits a multiplicity of phases among insects. In some species it is a rare, occasional phenomenon: in others it is the constant and normal method of reproduction, or

SNODGRASS, "SMITHSONIAN REPORT" (U.S. DEPT. OF AGRICULTURE)

FIG. 28.—PROTECTION OF THE INSECT EMBRYO WITHIN THE EGG

it may be cyclic—alternating with sexual reproduction. Parthenogenesis may, therefore, be classed under three headings: (1) *Sporadic*, which happens especially among moths and is more frequent in some species than in others: both males and females may be produced from the unfertilized eggs; (2) *Constant*: in social bees and wasps the males are regularly produced from the unfertilized eggs, and the same happens in many of the Chalcids. In some of the stick-insects females only are produced and the males are very rare: again, in certain gall-wasps and saw-flies males are unknown and sexual reproduction is consequently absent. (3) *Cyclic*: in

many gall-wasps and almost all aphides one or more parthenogenetic generations alternate with a sexual generation. In the gall-wasps the individuals of the two generations are often very different in form and produce dissimilar galls. The spring generation consists of females which give rise to a summer generation of both sexes which mate and produce the spring females of the next year. In aphides generation after generation of virgin females are

lular covering and, when mature, they separate and become free in the body of their host. The resultant insects may be female or male, according to whether the original egg was fertilized or not. As many as 3,000 larvae are known to issue from a single caterpillar of the Silver Y moth in which several of these chains of embryos were present.

GROWTH AND METAMORPHOSIS

After hatching or birth, insects undergo a process of growth and change till they become adult. Every insect during its growth sheds its cuticle several times, this process being known as moulting or *ecdysis*, the cast skin being the *exuvia*. The form assumed

SNODGRASS, "SMITHSONIAN REPORT" (U.S. DEPT. OF AGRICULTURE)

FIG. 29.—STAGES IN THE DEVELOPMENT OF THE DIGESTIVE CANAL OF AN INSECT EGG

produced viviparously till finally they give rise to true sexual individuals which pair and lay normal eggs.

Paedogenesis.—In a few insects larvae or pupae are capable of parthenogenetic reproduction, and this process, which involves the production of offspring by the immature animal, is termed paedogenesis. Thus, the pupae of an aquatic fly (family *Chironomidae*) have been known to produce eggs which duly hatched into larvae. In the gall-midge *Miastor*, the larvae regularly produce daughter larvae which eat their way out of the body of the parent and reproduce in a similar manner on their own account. After several generations of this type, male and female flies are usually produced which pair and their progeny gives rise to the paedogenetic cycle over again.

Polyembryony.—This consists in the production of two or more embryos from a single egg by a process of budding (fig. 31). It is only found in certain of those Hymenoptera whose larvae live as parasites in the blood and tissues of other insects. The simplest case is found in a minute creature *Platygaster hiemalis* which is a parasite of the Hessian fly. Some of the eggs of this parasite develop normally into larvae, while others develop up to a point when the embryo divides so as to produce two larvae within the same egg-covering. In other species ten or 12 larvae may arise from a single egg, while in some chalcid wasps which parasitize caterpillars, 100 or more larvae may be produced from a single embryo. These develop in a continuous chain enveloped in a cel-

AFTER HEYMONS,
ZEITS. WISB. ZOOL. 58

FIG. 30.—SECTIONS THROUGH THE ABDOMEN OF AN EMBRYO COCKROACH by an insect between successive moults is termed an *instar*: thus, when it issues from the egg it is in its first instar and after the second *ecdysis* it is in its third instar, and so on. The final instar is the fully mature insect or *imago*.

Metamorphosis.—Most insects issue from the egg in a different form from that assumed in the *imago* and in order to reach the latter condition, they have to pass through changes that are collectively termed metamorphosis. A small number of insects emerge

from the egg in their completed form and therefore do not undergo metamorphosis. Such insects are often termed *Ametabola*, spring-tails and bristle-tails being familiar examples. Certain other insects, which have lost their wings in their remote ancestry, have their transformations so reduced that they no longer merit the term metamorphosis. Such examples are consequently secondarily ametabolous and they exhibit only trivial differences between the young and adults: examples of this kind are found among stick-insects, lice, worker termites and other insects. The majority of insects, however, pass through a metamorphosis and may be

FIG. 31.—PLATYGASTER VERNALIS. SECTION THROUGH AN EGG OF PARASITIC HYMENOPTERON

a nymph, it never bears external rudiments of wings, and compound eyes are wanting.

Types of Metamorphosis.—From the foregoing remarks it will be noted that metamorphosis is of two types. In cases where the young insects are nymphs and there is no pupa, the change to the imago is direct and gradual, and metamorphosis is said to be incomplete (fig. 35). When the young insects are larvae which ultimately transform into pupae, metamorphosis is of an indirect and complex character and is said to be complete (fig. 33).

Types of Larvae.—Larvae issue from the egg in different stages of development which partly depend upon the amount of yolk that was available for their growth: generally, the less yolk there is the more immature are the larvae when they hatch. Larvae may be grouped under four types: (1) *Embryonic larvae*: these occur among some of the parasitic Hymenoptera whose eggs contain little or no yolk. They are so immature that they are little more than prematurely hatched embryos with an unsegmented abdomen and no appendages behind those of the thorax: the digestive and nervous systems are as yet rudimentary and the tracheal system is undeveloped. Such larvae live as parasites in the blood or other tissues of various insects and are thus surrounded by a highly nutritious food; (2) *Eruciform larvae*:

FROM HOWARD, "INSECT LIFE" (U.S. DEPT. OF AGRICULTURE)
FIG. 32.—NYMPH OF LOCUST
SCHISTOCERCA AMERICANA

these emerge from the egg at a much later stage when segmentation is complete and the internal organs are fully formed. Their special feature is the retention of a variable number of the embryonic abdominal appendages which are transformed into feet (fig. 33). Such larvae are known as caterpillars and are found in saw-flies, butterflies and moths; (3) *Campodeiform larvae* (fig. 34): larvae which bear this name are hatched in a form bearing a general resemblance to *Campodea* and other bristle-tails. They are carnivorous creatures that wander in search of their prey: the in-

tegument is well chitinized and the antennae, legs and cerci are prominently developed. In conformity with their active life, eyes and other sense organs are evident. Larvae of this type hatch late from the egg after the loss of the embryonic abdominal appendages. In many respects they resemble the nymphs of insects with incomplete metamorphosis, but are less advanced in their development. Campodeiform larvae are characteristic of ground beetles and Neuroptera; (4) *Vermiform larvae* (fig. 36): these are very

FIG. 33.—OWLET MOTH

varied in form and are worm-like or maggot-like with only vestiges of legs and antennae, or entirely legless. They are believed to be derived from the campodeiform type by degeneration induced by the presence of abundant food supply, which renders locomotory and sense organs of little value to the insect. Vermiform larvae occur in all flies, some beetles and in most Hymenoptera.

In addition to the foregoing there are many larvae that are of an intermediate character. Such larvae in general facies are campodeiform but in other characters incline towards the eruciform or, more usually, the vermiform type.

Ecdysis.—Since the cuticle is ill-adapted to accommodate itself to the increase in size of an insect consequent upon growth it is periodically shed. During each act of ecdysis not only the general cuticle covering the body and appendages is cast off, but also the cuticular lining of the tracheae, fore-gut and hind-gut. All these parts together with hairs, spines and similar structures are renewed by the activity of the hypodermal cells beneath them. Before moulting actually takes place special glands secrete a fluid

CHITTENDON, "BULLETIN OF ENTOMOLOGY" (U.S. DEPT. OF AGRICULTURE)
FIG. 34.—SAW-TOOTHED GRAIN-BEETLE

which penetrates between the old and new layers of cuticle and facilitates the final separation and rupture of the old skin. Spring-tails are the only insects that regularly undergo ecdysis after becoming adult, while may-flies undergo a moult on attaining the winged state, but before they are fully mature. In all other insects moulting is confined to the larvae and nymphs. Among the larvae of many flies and Neuroptera two ecdyses are very constant: in caterpillars moulting is variable, some may have nine ecdyses while in others it may be as low as three. In the may-fly *Chloeon*

23 ecdyses have been observed.

Growth.—The larval and nymphal periods are pre-eminently ones of growth and the increase in weight that is undergone in a short interval of time is remarkable. Among the influences that affect growth most profoundly are nutrition and temperature. Insufficient food, or food of the wrong nutrient composition, retards growth and consequently delays metamorphosis, and much the same effect is observable if insects be subjected to too low a

FIG. 35.—METAMORPHOSES OF CAPSID BUG

temperature. Under normal conditions of food and temperature a silkworm weighs, when fully grown, up to 10,500 times its weight when just hatched, and the caterpillars of the goat moth during a life of three years are stated to increase 72,000 times in weight in that period.

Hypermetamorphosis.—When an insect passes through two or more markedly different larval instars it is said to undergo hypermetamorphosis. This phenomenon is accompanied by a marked change in the life of the larva concerned. In most cases where this happens, the first larval instar is active and campodeiform, and in this condition the insect seeks its food. Having dis-

FIG. 36.—LARVA OF GOUT FLY

covered its pabulum it undergoes changes of form which adapt it to its subsequent mode of life. Hypermetamorphosis is evident in some beetles (see COLEOPTERA), in certain flies, in most of the groups of parasitic Hymenoptera (q.v.) and in some other insects.

Pupa.—Near the end of the larval period the insect prepares itself for transformation into the pupa, usually constructing a cocoon or other type of protection. A preliminary period of quiescence then follows when the insect is in a condition termed the *pre-pupa* (fig. 37). In this stage the wings and appendages first become evident outside the body, and its general form fore-

shows that of the imago. The pre-pupa is loosely enclosed in the old larval skin, and after the latter is moulted the true pupal condition is assumed. Since the pre-pupal and pupal instars are particularly vulnerable, either protection or concealment is necessary. It is only rarely that pupae are quite exposed as happens in those of many butterflies, but, in this case, protection is afforded by their colouration, which often closely assimilates with the natural surroundings. The larvae of many moths and beetles burrow in the ground when about to pupate, and then transform within earthen cells composed of soil particles, held together by an adhesive secretion. Numerous other insects construct cocoons of various extraneous materials woven together with a warp of silk, while in many moths the cocoons are formed entirely of silk: some of the most elaborate cocoons are those constructed by the great silkworm moths of the family Saturniidae. Among true flies there is seldom a cocoon and in those with a coarctate pupa, the latter is protected by being concealed below the soil, in refuse or other situations where the larval life was passed.

The term pupa is applied to the resting, passive stage in the life of insects with a complete metamorphosis, and during this instar it is incapable of feeding. The pupa is an acquired transitional phase during which the developing wings, legs and other append-

FIG. 37.—PRE-PUPAL STAGES

FIG. 38.—FULLY GROWN CATERPILLAR OF WHITE BUTTERFLY DISSECTED

ages of the future insect appear outside the body. Three types of pupae are generally recognized. In the *free pupa* (figs. 34 and 37) the wings and legs are free from any secondary attachment to the body, and such pupae have considerable capacity for movement. In mosquitoes and midges the pupae are aquatic, and are active swimmers: in certain other insects they are able to work their way above ground to facilitate the emergence of the perfect insects. The *obtect pupa* (fig. 33) has the wings and legs glued down to the body and there is but little freedom of movement: this type is characteristic of most moths. The *coarctate pupa*

(fig. 36) is found in all the higher groups of flies. In these insects the last larval skin is not cast off but remains outside the pupa as a hardened shell forming a capsule or puparium.

Emergence from the Pupa.—As the time approaches for the eclosion of the perfect insect the pupa noticeably darkens, and in many butterfly pupae, the colours of the contained insect are distinctly observable at this time. During the act of emergence the insect usually ruptures the pupal cuticle in a longitudinal fracture down the back of the thorax, and draws itself out. It then crawls up the nearest available support and rests with its miniature wings hanging downwards. By the influx of blood from the body the wings assume their full size and, after a period of rest when all the parts become hardened, the insect is able to make its first flight. When a cocoon is present the insect often has to bite its way through the walls by means of its jaws as in Coleoptera and Hymenoptera, but in caddis-flies and Neuroptera, the pupa bears mandibles for this purpose; various other methods of emergence from the cocoon are mentioned in the article LEPIDOPTERA.

Development of the Perfect Insect.—The culminating point of metamorphosis is the actual formation of the imago. In insects with incomplete metamorphosis this is accomplished by a gradual process of growth changes, both internal and external, during successive nymphal instars till the adult condition is attained. In insects with complete metamorphosis, it has been seen that a pupal stage has been intercalated in the life-cycle, and it is during this instar that profound change occurs. Outwardly inactive, the pupa is in reality the seat of intense activity within. The formation of the imago begins in the larva and is initiated by the development of new growths termed imaginal buds, which gradually build up all the parts that require reconstruction to serve the needs of the future insect, as well as forming all organs unrepresented in the larva. Imaginal buds which form the legs, wings, mouth-parts and other external organs, are derived from the hypodermis and some of them can be seen by careful dissection of a fully grown caterpillar (fig. 38). The buds which form the internal organs arise from nests of cells in special locations within the existing larval organs, and by their growth and extension build up the new parts necessary. In some insects such as beetles and Neuroptera the internal changes are often relatively simple, but in ants, bees and many flies they are extremely complex. It is during the pupa that the unwanted larval organs have to be broken down and replaced by new growths, and the amount of reconstruction required depends upon how far the structure and functions of the imago differ from those of the antecedent larva. In the blow-fly, for example, practically all the larval organs are broken down in the pupa, and their residue, as it were, serves as nutriment for developing new growths. The actual method of destruction of the larval organs has given rise to much discussion, but most authorities maintain that wandering blood cells, or phagocytes, play an active part, and in fig. 39 are seen certain of the phagocytes destroying a larval muscle. In other insects it is believed that phagocytes

FROM PEREZ, "MÉTAMORPHOSE DES MUSCIDES" (LIBRAIRIE H. DE SODIER)
FIG. 39.—DESTRUCTION OF LARVAL MUSCLE BY PHAGOCYTES IN PUPA OF BLOW FLY

either perform a less important part in the process, or take no part at all, and that physiological changes induce the organs concerned to degenerate and break down.

CLASSIFICATION AND DISTRIBUTION

The number of described species of insects exceeds 450,000 and though several thousand new ones are discovered yearly, it is believed that the unknown species remain an enormous majority. The classification of this vast assemblage of forms has undergone many changes since Linnaeus' time, though five of his orders are recognized to-day. Most of the classificatory schemes that have been proposed are based primarily upon characters afforded by the mouth-parts, wings and metamorphosis. As many as 37 different orders are adopted by some authorities, but the most generally accepted systems are more conservative in this respect. The classification here adopted includes the following 23 orders (an asterisk indicates a separate article on the subject).

CLASS: INSECTA

Sub-class: APTERYGOTA*

Primitively wingless insects with no true metamorphosis. Abdominal appendages present other than gonopophyses and cerci.

Order I. Thysanura.—Small insects with long, many jointed antennae: abdomen of ten segments and bearing prominent cerci. Includes the bristle-tails.

Order II. Protura.—Very minute insects without antennae: abdomen of 12 segments, cerci wanting.

Order III. Collembola.—Very small insects with four-jointed antennae: abdomen of six segments, sometimes fused together, the first with a sucker-like ventral tube and the fourth usually with a forked springing organ. Includes the spring-tails.

Sub-class: PTERYGOTA

Winged insects (sometimes wingless through loss of flight organs): metamorphosis more or less evident. No abdominal appendages other than genitalia and cerci.

Division I.: EXOPTERYGOTA

Wings developed outside the body: metamorphosis incomplete or scarcely evident in the wingless species.

Order IV. Orthoptera*.—Fore-wings leathery, hind-wings membranous with posterior lobe folded up fan-wise. Prothorax large: mouth-parts for biting, with four-lobed ligula: cerci present. Includes cockroaches, grasshoppers, locusts, crickets, stick-insects and leaf-insects: some forms are wingless.

Order V. Dermaptera.—Fore-wings small leathery flaps, hind-wings large, membranous, complexly folded up. Mouth-parts for biting, with two-lobed ligula: tarsi three-jointed: the body terminated by forceps. Includes the earwigs (*q.v.*), many of which are wingless: also *Hemimerus* and *Arixenia* which are rare wingless forms, without forceps, living on mammals.

Order VI. Plecoptera* (Perlaria).—Soft-bodied insects with long thread-like antennae; wings membranous, folded flat over the back in repose; the hind pair usually largest and with a posterior lobe folded up fan-wise. Mouth-parts for biting, tarsi three-jointed: cerci often elongate. Nymphs aquatic, often with tufted gills. Includes the stone-flies.

Order VII. Ephemeroptera (Plectoptera).—Soft-bodied insects with atrophied mouth-parts and minute antennae. Wings membranous, net-veined, hind pair much the smaller: tarsi one-to five-jointed: cerci long, many-jointed and often accompanied by a median tail-filament. Nymphs aquatic with tracheal gills. Includes the may-flies (*q.v.*).

Order VIII. Odonata (Paraneuroptera).—Large insects with very elongate bodies, large eyes and minute antennae. Two pairs of equal, membranous, net-veined, glassy wings. Mouth-parts for biting: tarsi three-jointed: cerci small, one-jointed. Nymphs aquatic, labium modified into a hinged prehensile organ. Includes the dragon-flies (*q.v.*).

Order IX. Isoptera.—Social insects living in large nests: soft-bodied and generally pale coloured: either with two pairs

of elongate similar wings which are soon shed, or without wings. Mouth-parts for biting: tarsi almost always four-jointed: cerci very short. Wingless forms with rudimentary eyes or none at all and usually of two types: viz., soldiers with large heads and jaws or a pointed rostrum, and workers with normal heads and jaws. Includes the termites (*q.v.*) or white ants. (See also SOCIAL INSECTS.)

Order X. Embioptera.—Soft-bodied insects with two pairs of elongate, smoky wings of equal size and with degenerate veins. Mouth-parts for biting: tarsi three-jointed, first joint of fore-pair greatly swollen: cerci, short two-jointed. Females almost always wingless. A small group of insects often living gregariously in silken web-like tunnels and inhabiting warm countries. (See SOCIAL INSECTS.)

Order XI. Psocoptera (Corrodentia).—Very small soft-bodied insects, winged or wingless: wings membranous with few veins, anterior pair the larger with extensive stigma. Mouth-parts for biting: tarsi two- or three-jointed: cerci wanting. Includes the book-lice and their allies. The small recently discovered group Zoraptera are sometimes included here.

Order XII. Anoplura.—Very small tough-bodied, flattened, wingless insects living on mammals or birds, with short three- to five-jointed antennae: eyes reduced or wanting. Mouth-parts highly modified either for biting or piercing: tarsi one- or two-jointed: cerci wanting. Includes the true lice or Siphunculata and the bird-lice or Mallophaga. (See LOUSE.)

Order XIII. Thysanoptera*.—Minute and very slender insects with short six- to nine-jointed antennae and very narrow wings with long hair-fringes: mouth-parts stylet-like, for piercing: tarsi very short, one- or two-jointed, terminated by a small bladder-like organ: cerci wanting. Metamorphosis with a rudimentary pupal stage. Includes the thrips.

Order XIV. Hemiptera*.—Mouth-parts for piercing and sucking with mandibles and first maxillae stylet-like and lying in a jointed, grooved rostrum formed by the labium. Wings very variably developed, with but few veins, and often wanting. Prothorax large: tarsi with rarely more than three joints: cerci absent. An incipient pupal stage present in some cases. Includes the plant-bugs, cicadas (*q.v.*), leaf-hoppers, frog-hoppers, aphides (*q.v.*) and scale insects.

Division II.: ENDOPTERYGOTA

Wings developed inside the body until the pupal stage, metamorphosis complete.

Order XV. Neuroptera*.—Small to rather large soft-bodied insects with two pairs of usually sub-equal, membranous, net-veined wings which are closed roof-like over the body when at rest: hind-wings without a plicated posterior lobe. Mouth-parts for biting: tarsi five-jointed: cerci absent. Larvae campodeiform, terrestrial or aquatic: pupae free, usually in a silken cocoon. Includes the alder-flies (*q.v.*), ant-lion flies (*q.v.*), mantis flies, lace wings and mealy wings.

Order XVI. Coleoptera*.—Fore-wings modified into horny elytra which meet in a straight line down the back, the hind-wings (where present) membranous and folded beneath them. Prothorax large: mouth-parts for biting: cerci absent. Larvae of various types: pupae free, rarely in a cocoon. Includes the beetles.

Order XVII. Strepsiptera.—Minute insects: the males with branched antennae and degenerate biting mouth-parts. Fore-wings minute club-like scales: hind-wings very large, membranous and plicately folded. The females inert degenerate sac-like parasites living in the bodies of other insects includes the stylops (*q.v.*) and its allies.

Order XVIII. Mecoptera.—Soft-bodied insects with two pairs of similar membranous wings folded flat over the back in repose. Head generally prolonged into a beak: mouth-parts for biting: short cerci present. Larvae eruciform: pupae free, not in a cocoon. Includes the scorpion flies (*q.v.*) and their allies.

Order XIX. Trichoptera*.—Moth-like insects with two pairs of membranous hair-covered wings, with predominantly longitudinal venation: hind pair usually the larger with a plicate

posterior lobe. Mouth-parts imperfect, mandibles wanting. Larvae aquatic, more or less eruciform, living in cases: pupae free, with strong mandibles. Includes the caddis flies (*q.v.*).

Order XX. Lepidoptera*.—Small to very large insects usually densely clothed with flat scales. Mouth-parts suctorial: first maxillae usually modified into a spirally coiled proboscis: mandibles almost always absent. Larvae terrestrial, eruciform, with several pairs of abdominal feet: pupae obtected or partially free, usually in a cocoon. Includes the butterflies and moths.

Order XXI. Diptera*.—Insects with a single pair of membranous wings: hind pair modified into minute knobbed organs or halteres: rarely wingless. Mouth-parts for sucking or for piercing also, and elongated to form a proboscis. Larvae vermiform: terrestrial, or parasitic or more rarely aquatic: pupae free or coarctate. Includes the true flies (*q.v.*).

Order XXII. Siphonaptera. (Aphaniptera).—Very small wingless insects, laterally flattened, with tough integument. Mouth-parts for piercing and sucking. Blood-sucking parasites living on warm-blooded animals. Larvae vermiform: pupae free, in a silken cocoon. Includes the fleas (*q.v.*).

Order XXIII. Hymenoptera*.—Wings tough and membranous: hind pair the smaller and connected with fore pair by a series of minute hooks. Mouth-parts for biting and licking: labium usually modified into a tongue of variable length. Prothorax small and ring-like: abdomen usually basally constricted to form a waist, its first segment fused with the thorax: a sawing or piercing ovipositor present. Larvae eruciform or vermiform but sometimes embryonic: pupae usually in a cocoon. Includes the saw-flies, ants, bees, wasps and ichneumon flies and their allies (*qq.v.*): see also SOCIAL INSECTS.

Geographical Distribution.—The class Insecta as a whole, is cosmopolitan as are almost all its individual orders. The range of any great group of animals is governed by many factors, whose individual effects are difficult to evaluate separately. In the case of insects the possession of wings is a feature of supreme importance, since it imparts to its possessors a capacity for dispersal lacking in other terrestrial animals not so endowed. The power to disperse freely allows a species to escape from intense competition, and the effects of rigid selection which results from overcrowding within limited areas. Habits and food-supply are clearly also highly important: aquatic insects cannot exist where there is no water and bark beetles are not to be found on steppes or plains devoid of all trees. Yet, on the other hand, many insects have a distribution much more restricted than their available food, climatic and other barriers precluding their spread. High mountain ranges may present insuperable obstacles by way of climate and changed vegetation, while deserts and oceans are even more powerful barriers to the dispersal of almost all insects. Many facts of distribution, however, cannot be interpreted under present conditions of the earth's topography and climates, and recourse has often to be made to a study of geological changes. The close similarity of the insects of Europe and North America, for example, is explained on the basis of a former more favourable climate in the Arctic region, when it did not interpose as a barrier to dispersal as happens under the frigid conditions of to-day. The presence of allied spring-tails in New Zealand and Chile suggests a former extension of the Antarctic continent between them, since such delicate insects can scarcely be credited to have attained their present distribution by other means. There are again insects which exhibit a wide but discontinuous distribution, such groups often appearing to be scattered remnants of forms which once enjoyed an extensive, continuous range, but now widely separated by climatic or topographic changes. Moths of the family *Uraniidae* and butterflies of the genus *Erebia* exhibit a distribution of this character.

Some individual insects are almost cosmopolitan and possess great capacity for migration and of adaptation to changed conditions. Examples of such species include the hawk-moth *Celerio lineata*, and the butterflies *Pyrameis cardui* and *Anosia plexippus*. The extensive distribution of the spring-tail *Hypogastrura armata* has been accounted for on the basis of former land-connections between certain of the great continents, as already alluded to. Other cosmopolitan insects such as the house-fly and many beetles

affecting grain and other stored products have attained their wide dispersal through human agencies.

The spring-tails have the widest range of any group of insects and have adapted themselves to the greatest diversity of surroundings, while ants approach them very closely in these two respects. Ants, as W. M. Wheeler remarks, are found "from the Arctic regions to the Tropics, from timber line on the loftiest mountains to the shifting sands of the dunes and sea-shores, and from the dampest forests to the driest deserts." More detailed facts relative to insect distribution are given in the separate articles devoted to the principal orders.

Geological Distribution.—Insects are relatively scarce as fossils and are only found in certain geological formations especially favourable for their preservation. Most of the specimens probably originally got drowned, and were quickly covered with silt or other deposits before they had time to decay; consequently the richest remains occur in vegetable deposits such as coal, lignite and peat, and in ancient fresh-water basins. A great many also occur in amber where they became entangled in the resin, which quickly enveloped them, thus securely sealing them up in a wonderful condition of preservation. Among the most famous localities for fossil insects are the Carboniferous rocks of Commeny, France, the Permian beds of Kansas and of New South Wales, the Triassic beds of Queensland, the lithographic limestones of Jurassic age in Bavaria, the Oligocene shales of Florissant in Colorado, the Miocene beds of Oeningen in Bavaria and Baltic amber of the same period.

The study of fossilized remains indicates that no undisputed insect has been found earlier than Upper Carboniferous times and even these very ancient insects were already highly evolved, affording little information as to the ancestry of the class as a whole. The oldest known insects are all Exopterygota and comprise totally extinct orders, some of which are allied to the existing Orthoptera and others (Palaeodictyoptera) exhibit the combined characters of several of the most generalized living orders; included among these fossils are also ancestral dragon-flies of gigantic size. The only still existing insects represented in Carboniferous times are the cockroaches, which have persisted with relatively little modification through the intervening ages to the present day. In Lower Permian times the first true dragon-flies appear, with Ephemeroptera, Hemiptera and some anomalous insects (Protohymenoptera), which are regarded as the far-off ancestors of the Hymenoptera. In rocks of this age there are also found the earliest remains of the Endopterygota which are represented by some small species of Mecoptera. In the Upper Permian are found the first recorded Coleoptera and Neuroptera together with some remarkable insects (Paramecoptera) which are held to be the ancestors of Lepidoptera, Trichoptera and Diptera. It is not until Jurassic times that true Diptera and Trichoptera appear, while Hymenoptera are first found in the Cretaceous and the oldest Lepidoptera are of Oligocene age. In rocks of later date the insect remains are very like those of living forms and those found in Baltic amber even belong to existing genera.

A survey of fossil insects shows that the Exopterygota appeared first and though no remains of the most primitive insects (Thysanura) have been found till Tertiary times, it is probable that their delicate organization has not favoured their preservation through the great periods of time when they presumably were existing. Although the Endopterygota are of great antiquity, those orders which are most specialized and exhibit the greatest differences between the larva and the imago were the last to appear. Further details respecting fossil insects will be found in separate articles dealing with the principal orders.

NATURAL HISTORY

The Life-cycle.—In temperate and cold regions the life-cycle of most insects involves a period of dormancy or hibernation during the winter months, whereas in the uniform hot and moist climate of the Tropics, hibernating does not exist and one generation succeeds the other without any such dormant period. Hibernation may take place in any stage in the life-cycle in different insects. Among British butterflies, for example, the Hairstreaks

hibernate as eggs, the White Admiral, Fritillaries, etc., overwinter as larvae, the garden whites and others as pupae and the Brimstone, Peacock and Tortoiseshells pass the winter as perfect insects, sheltering in old buildings, hollow trees and other likely situations.

Some insects such as the Cotton Boll Weevil may pass through as many as eight generations in the year, while on the other hand, the click beetle (*Agriotes obscurus*) requires about five years to complete a single generation, most of that period being spent as a larva. The house-fly under favourable conditions of food, temperature and moisture can complete its life-cycle in ten days, but the shortest cycle is found in some minute Chalcid wasps whose larvae live as parasites in the eggs of other insects, and require only seven days from when their eggs are laid till the perfect insects appear.

Plant-relations.—A vast number of insects only exist in association with vegetation and every kind of phanerogamic plant, and every part of the plant may serve as food for one or other species of insect. Larvae of moths, saw-flies and many beetles feed openly and devour the foliage, and other larvae live concealed within the leaves, stems, roots or the solid wood. Thrips, aphides and other plant-bugs pierce the plant-tissues and extract the sap. There are also insects which confine themselves to devouring the flowers, seeds or even the pollen, while bees and many moths and flies imbibe nectar. There are again other insects which, instead of destroying plants, modify them in such a way as to produce abnormal growths, or galls, which serve as food and shelter for their larvae. Most galls are produced by gall-wasps (*Cynipidae*), gall-midges (*Cecidomyiidae*) and certain saw-flies while a few are produced by beetles, aphides and other insects. The actual cause of gall-formation has been much discussed and these growths are due to the activity of the meristem under the influence of a definite stimulus. In some cases gall-formation follows immediately after the insect has laid its eggs in the plant-tissues and in these instances it is believed to be due to a secretion injected into the plant at the time of egg-laying, since the gall develops after the egg has been killed by puncturing with a needle. In other cases it is induced by the presence of the larva, the gall not developing till after the insect has issued from the egg.

The relationship between insects and flowers is mutually beneficial: insects obtain nectar and pollen and in return ensure cross-pollination by transferring the pollen from the stamens of one flower to the stigma of another. Flower-haunting insects often exhibit special structural modifications enabling them to suck nectar from deeply seated nectaries, and bees are provided with organs for pollen-collecting. Flowers in their turn are coloured or otherwise ornamented to attract insect-visitors and their scents are believed to serve the same purpose. Most flowers are also so constructed that insects inevitably pollinate them, and many such as orchids, iris, yucca, etc., are formed so that pollination is effected in a particular manner.

Among the lower plants affected by insects, fungi of various kinds afford sustenance and shelter to many small beetles and their larvae, along with those of fungus-midges and other flies. Certain of the primitive fungi are pathogenic to insects, entering and spreading within their bodies and ultimately killing them. Mention needs also to be made of species of ants and termites which cultivate fungi within special recesses of their nests where they serve to feed the brood. Lichens are fed upon by various moth larvae, but liverworts, mosses and ferns support comparatively few insects.

Scavengers.—Not only living plants afford food and shelter for insects, but decaying vegetable matter is also resorted to by a vast number of beetles and flies, together with certain of the spring-tails. Dung affords sustenance for many insects as well as decomposing carcasses and animal remains of all kinds. In a large degree the activities of scavenger insects are beneficial in facilitating the rapid decomposition of all kinds of decaying material.

Aquatic Insects.—A considerable number of insects are aquatic and are found in fresh water, while a few occur in saline waters and in the sea. Among fresh-water insects some are aquatic

throughout their life, notably beetles of the family *Dytiscidae*, which live habitually submerged, and water-bugs or pond-skaters (*Hydrometridae*) which are surface dwellers. The Whirligig beetles (*Gyrinidae*) live submerged as larvae, but the adult beetles congregate in companies on the surface. A far greater number of insects are aquatic only in their immature stages, the adults being aerial: familiar examples are midges, mosquitoes, stone-flies, may-flies, caddis-flies and dragon-flies.

All aquatic insects are believed to have been derived from terrestrial ancestors and have become adapted in diverse ways to their special mode of life: these adaptations mainly concern locomotion and respiration. Among beetles and water-bugs the swimming legs are flattened and oar-like, often fringed with closely set hairs, and form efficient paddles. Respiratory modifications are numerous and in pond-skaters the body is clothed with a dense velvety pile which renders them incapable of being wetted, and also serves to retain a coating of air around the insect when submerged: in this manner a supply of oxygen is provided for breathing and the insect can remain immersed till it is used up. Some beetles carry a supply of air beneath the elytra when submerged, while others descend with a bubble of air at the apex of the abdomen. Water-scorpions are provided with a kind of caudal respiratory tube and, when necessary, protrude the apex of this siphon through the surface film: air passes down this channel to enter a pair of spiracles situated at its base. Mosquito larvae breathe by means of a caudal siphon of a different character: it bears a pair of spiracles at its apex and air enters the tracheal system directly, when the siphon breaks the surface film. Many other insects breathe the oxygen dissolved in the water: such insects either possess gills or respire cutaneously. Gills are outgrowths of the integument containing tracheae or more rarely only blood. In may-fly nymphs (fig. 40) they are commonly in the form of lamellae attached to the sides of the abdomen, while in many dragon-fly nymphs they lie within the terminal chamber of the gut, water being inhaled and exhaled through the anus. The so-called bloodworms or larvae of certain midges (*Chironomidae*) are remarkable in that the blood contains haemoglobin and respiration takes place through the skin.

The open sea is almost devoid of insect life excepting for a few midge larvae that have been dredged from tolerably deep water and the Hemipterous genus *Halobates* which frequents the surface of warm oceans often far from land. Between tide levels the shore is inhabited by the spring-tail *Anurida maritima*, a few beetles and their larvae and certain flies. These insects, or at least their larvae, are immersed during each tide when they retreat under stones or in the sand, while some midge larvae remain continuously submerged. Those of the European genus *Clunio* occur in rock pools along with the curious wingless females, while the males, which are winged, skim over the water surface. Loss of wings is a common feature of marine insects and it has been explained as an advantage which prevents such insects being blown out to sea.

Predators and Parasites.—There are diverse groups of insects that have adopted close relations with respect to food and shelter not only with other insects, but also with vertebrate animals. Many insects such as ground beetles and their larvae are predators which seek out and devour other insects as food: or the relations may be of a closer nature and the prey becomes the host, as happens in the case of parasites. Some parasitic insects live externally on their hosts and are termed *ectoparasites*, while others—*endoparasites*—live within the bodies of their hosts. Fleas and lice, for example, are ectoparasites of warm-blooded animals from whose bodies they extract blood as their food. The grubs of warble flies are endoparasites of mammals, while those of Ichneumon flies and

Tachinid flies live within the bodies of other insects which they finally kill. Some very minute Hymenoptera are endoparasites of the eggs of various insects, finding therein sufficient nutriment to complete their transformations: other parasites attack only larvae or pupae and a few confine themselves to adult insects. A parasite may, in its turn, be parasitized by smaller insects of similar behaviour which are termed secondary parasites or *hyperparasites*; tertiary or even quaternary parasites are also known and provide the most complex examples of hyperparasitism.

Parasitic insects exhibit varying degrees of adaptation to their mode of life: some ectoparasites are very little modified except that their claws are specially developed for clinging to their hosts and wings are totally absent. Among endoparasites all traces of limbs and sense organs are wanting, these degenerative changes being adaptations to a life in which the necessity to seek out food is no longer present. The tracheal system is often totally absent but, on the other hand, the integument is unusually thin so as to allow of the passage of oxygen contained in the blood of the host, at whose expense such parasites feed and respire. During most of their life endoparasites avoid the vital organs of their hosts and feed largely upon the blood and fat-body, since their own death would speedily follow that of the insects they parasitize: for the same reason such parasites do not void the contents of the gut till the last moult. One of the most advanced types of parasitism is found in the stylops and its allies where the female, after issuing from the egg, spends its whole life as an endoparasite in the body of a bee or a leafhopper. The adult is a degenerate sac-like creature specially adapted for this mode of life. The male stylops is a parasite only as a larva and finally emerges as an active winged insect.

Inquilines.—Certain insects instead of devouring others feed at their expense and are termed inquilines. The latter are numerous in the nests of social insects and a well-known example is the wax-moth whose larvae live in bee-hives and destroy the comb.

FIG. 40.—NYMPH OF MAY-FLY

FROM HEYMONS, "ZEITSCHRIFT FÜR WISSENSCHAFTLICHE ZOOLOGIE" (AKADEMISCHE VERLAGSGESELLSCHAFT)

FIG. 41.—MORPHOLOGY OF AN INSECT

Larvae of the hover flies (*Volucella*) live in the nests of bumblebees and wasps, where they feed on waste organic material. The curious bristle-tail *Ateuchus* occurs in ants' nests and is stated to live by imbibing the food which is being actually regurgitated from one ant to another. There are again other insects which benefit their hosts in return for their keep. Thus, certain beetles obtain food and shelter in ants' nests and provide the ants in return with cutaneous secretions that are much sought after by their hosts. In extreme cases the association is even more intimate, the guest beetles being actually fed by the ants in return for the secretions

provided, thus affording an example of symbiosis or mutual benefit. (See SOCIAL INSECTS.)

Gregariousness and Social Life.—Although the vast majority of insects are solitary in habit, individuals of certain species associate together collectively and are said to be gregarious. Whirligig beetles, for example, associate in companies on the surface of the water: locusts and some butterflies become gregarious when migrating and ladybirds at times congregate in masses. Some caterpillars are gregarious and members of a brood live in a common web spun over the food-plant: such companies usually disperse, as the food becomes used up, and its members live independently. There are again other insects such as the earwig and the mole cricket in which the female guards the eggs and the young brood. A solitary bee of the genus *Halictus* constructs its cells in a group around a common entrance tunnel in the ground: these cells are provisioned and guarded by the parent, who may even survive till the daughter bees emerge. Examples of this kind where the parent guards and tends the offspring, at least during their early life, foreshadow the beginnings of social life. The latter exhibits its own peculiar features in different groups of insects which have developed the social habit, but in all cases each society is a family consisting of two parent insects, or at least the fecundated female, and the offspring, and the members of the two generations live together in a common abode or nest in mutual co-operation. True social insects include several groups of wasps and bees, together with the ants and termites. In the highest grades of social life specialization of certain individuals to perform specific functions for the common good is attained and a system which exhibits striking parallels in behaviour with human society has been developed. (See SOCIAL INSECTS.)

PHYLOGENY

Ancestry of Insects.—It is conceded that the most primitive insects are the bristle-tails (*Thysanura*) and these lowly creatures betray certain characters which are to be regarded as inheritances from an ancestral stock. The embryonic development of insects also reveals primordial characters: the evanescent appendages just behind the antennae and those borne on the abdominal segments in generalized insect embryos, indicate that the ancestors of insects carried five pairs of head appendages and had a body of 15 segments, all of which except the last bore limbs. Those carried on the first three body segments (legs of insects) and on the 14th segment (cerci) were evidently more important than the intervening pairs, of which traces only remain in some larvae and in the Apterygota. It seems clear, therefore, that the ancestors of insects were many-legged animals and the nearest approach to such progenitors is to be found in certain small, white creatures living in moist earth and represented by *Scolopendrella* and its allies. They form the class Symphyla which is related to the Chilopoda (centipedes) and Diplopoda (millipedes). Structurally the Symphyla have so many features in common with such bristle-tails as *Campodea* and *Anajapyx* as to justify affinity between the two groups. Other Thysanura, such as *Machilis* and its allies, show features in common with the higher crustacea particularly with regard to the mouth-parts. It must also be remembered that the small evanescent appendages found behind the antennae in some insect embryos, are to be regarded as relics of the second pair of feelers only found in Crustacea. The foregoing remarks indicate very briefly that it is probable that the ancestors of insects had features in common with the Symphyla and through them with the Chilopoda and Diplopoda, but at the same time, these ancestors were derived from a stock from which the Crustacea also arose. The Arachnida, or spiders and scorpions, are only very remotely related to insects and evidently diverged very early in their evolution from the primordial arthropod stock. (See also ARTHROPODA.)

Origin of Wings.—The Thysanura are eminently terrestrial insects, devoid of wings, and undergo no metamorphosis. Since they are the most primitive known insects and the majority of that class are winged creatures, the derivation of the latter from the Thysanura is largely involved in the origin of wings. Many authorities believe that wings first arose as small lateral expansions of the tergal region of the thoracic segments. During their evolution these expansions became sufficiently large to function after

the fashion of parachutes in insects which possessed a tendency to leap. At a later stage they acquired direct articulation with the thorax, became supplied with tracheae and developed the power of independent motion. By others it is contended that wings were derived from plate-like thoracic tracheal gills which had lost their original function and became adapted for purposes of flight. Such gills, it is maintained, resemble those found in many may-fly nymphs, and the theory implies that the ancestors of winged insects became temporarily aquatic and thus acquired gills, which developed into wings when their possessors resorted to the land for a second time.

Relationships of the Orders of Insects.—The most generalized orders of winged insects are all included in the division Exopterygota, but among this assemblage of forms several divergent lines of evolution are evident. The Orthoptera are the most primitive living winged insects and were probably more or less directly derived from Thysanuran ancestors. The Dermaptera, Isoptera and Embioptera are all more closely related to the Orthoptera than to any other order of insects. The Plecoptera exhibit many primitive features allying them with the Orthoptera, but their immature stages are aquatic as are those of the Odonata and Ephemeroptera. The two latter orders exhibit certain mutual relationships and are to be regarded as rather isolated developments from original Orthopteran ancestors. The Hemiptera and Thysanoptera have much in common: both orders are highly specialized with piercing mouth-parts and although originally descended from insects with jaws of the normal biting type, they have left little trace of their original lines of evolution. The Anoplura are degenerate parasites which are perhaps related through the Psocoptera with Orthopteroid ancestors. The Endopterygota are more closely related to each other than to any of the Exopterygota and no connecting links between the two divisions have so far been discovered. It is true that an incipient pupal stage is present among Termites and in some of the Hemiptera, and even among certain members of the latter order the wings develop internally, but these instances appear to be rather nature's experiments towards an endopterygote condition than evidence of lines of descent of any of the true endopterygote orders. The fossil order Paramecoptera appears to be the forerunner of almost all the higher orders of insects and the direct ancestors of the existing Mecoptera. The latter, along with the Neuroptera, Lepidoptera, Trichoptera and Diptera, form an interrelated complex, which attains its highest specialization in the last-mentioned order. The Hymenoptera lie outside this complex but there appears to be evidence that the fossil order Prothymenoptera is the far-off progenitor of the group, and possibly serves to connect them with a Paramecopteran stock. The Coleoptera and the related Strepsiptera exhibit little or no indications of their affinities: the campodeiform larvae of many beetles are primitive in type and not unlike those of Neuroptera and it is probable that the order arose as an early offshoot in the endopterygote series. The Siphonoptera or fleas likewise leave little trace of their descent, but in their metamorphoses they come nearer to the Diptera than to any other order and they are accorded a position next to the Diptera in the more generally accepted recent systems of classification.

See the articles COLEOPTERA; DIPTERA; HEMIPTERA; HYMENOPTERA; LEPIDOPTERA; NEUROPTERA; ORTHOPTERA; PLECOPTERA; THYSANURA; TRICHOPTERA.

BIBLIOGRAPHY.—The literature on insects has assumed enormous proportions and at least 2,000 scientific books, memoirs and separate articles appear each year in various languages, apart from writings of a popular character.

General Text-books.—Among the best elementary manuals to be found on the subject are: J. W. Folsom, *Entomology with special reference to its Ecological Aspects* (1923); G. H. Carpenter, *Insects: their Structure and Life* (1924); W. H. Wellhouse, *How Insects Live* (1926). For a larger book, D. Sharp, "Insects" in the *Cambridge Natural History* (vols. v., vi., 1895, 1898) is important.

General text-books of a more advanced character include: L. F. Hennequy, *Les Insectes* (1904); the great work of A. Berlese, *Gli Insetti* (Milan, 1909-25); C. Schröder, *Handbuch der Entomologie* (Jena, 1912-28); J. H. Comstock, *Introduction to Entomology* (1920); A. D. Imms, *General Text-book of Entomology* (1925); all these works contain copious bibliographies.

There are also a number of books which, although containing general

information, deal more especially with the insects of a specific country or region. The most important are V. L. Kellogg, *North American Insects* (1905); H. M. Leiray, *Indian Insect Life* (Calcutta, 1909); T. B. Fletcher, *South Indian Insects* (Madras, 1914); R. J. Tillyard, *Insects of Australia and New Zealand* (Sydney, 1926); E. O. Essig, *Insects of Western North America* (1926).

Palaeontology.—For fossil insects, G. Brongniart, *Recherches pour servir à l'Histoire des Insectes Fossiles des Temps primaires* (St. Etienne, 1894) and A. Handlirsch, *Die Fossilen Insekten* (Leipzig, 1908) are standard works. Reference should also be made to the last-mentioned author's article on the subject in the text-book of Schröder (*loc. cit.*), and to numerous papers by R. J. Tillyard in *Proceedings of the Linnean Society of New South Wales* and in *American Journal of Science*.

Embryology.—The most accessible works on this subject are E. Korshelt and K. Heider, *Text-book of the Embryology of Invertebrates*, vol. iii. (1899; English trans. by Bernard and Woodward); E. W. MacBride, *Text-book of Embryology*, vol. i. (1914); J. H. Nelson, *The Embryology of the Honey Bee* (Princeton, N.J., 1915), which contains a full bibliography.

Biology, etc.—Works on the metamorphoses, habits and behaviour of insects are numerous and mention needs to be made of J. H. Fabre, *Souvenirs Entomologiques* (1879-1905; English trans. of many); A. Forel, *The Senses of Insects* (1908; English trans. by Yearsley); G. H. Carpenter, *Insect Transformation* (1922); the various parts of the *Biologie der Tiere Deutschlands*, ed. by P. Schultze (Jena, 1922-27) are excellent and well illustrated; E. L. Bouvier, *The Psychic Life of Insects* (1922; English trans. by L. O. Howard); W. M. Wheeler, *Social Life among the Insects* (1923).

Among books dealing with certain of the more specialized aspects of insect life, those of an ecological nature include V. E. Shelford, *Animal Communities in Temperate America* (Chicago, 1913); G. D. H. Carpenter, *A Naturalist on Lake Victoria* (1920); P. A. Buxton, *Animal Life in Deserts* (1923); R. N. Chapman, *Animal Ecology with special Reference to Insects* (Minneapolis, 1926).

Works on aquatic insects include various parts of the *Süsswasser-fauna Deutschlands*, ed. by Brauer (Jena, 1909); L. C. Miall, *Natural History of Aquatic Insects* (1912); F. Brocher, *L'Aquarium de Chambre* (1913), which is a most interesting book; H. B. Ward and G. C. Whipple, *American Freshwater Biology* (1918); E. Rousseau, *Les Larves et Nymphes aquatiques* (1921).

For insects in relation to plants see E. Houard, *Les Zoocécides des Plantes d'Europe* (1908-13); E. T. Connold, *Plant-Galls of Great Britain* (1909); F. Knoll, *Insekten und Blumen* (1921-26); M. Hering, *Die Ökologie der blattminieren Insektenlarven* (1926).

For the various aspects of parasitism and symbiosis the best introduction is M. Caullery, *Le Parasitisme et la Symbiose* (1922).

For luminous insects see E. N. Harvey, *The Nature of Animal Light* (Philadelphia, 1920), and for cave insects consult R. Jeannel, *Faune Cavernicole de la France* (1926).

Periodical Literature.—Periodicals devoted to the study of insects are exceedingly numerous and are published in many languages. Some of the more important are mentioned in the article ENTOMOLOGY. (A. D. I.)

INSEIN, a town and district of Lower Burma in the Pegu division, lying immediately to the north of Rangoon. Area 1904 sq.m.; pop. (1921) 293,083. The district includes a large tract of the Irrawaddy delta on either side of the Hlaing or Rangoon river and on the east of the Irrawaddy itself. In the west the district includes a portion of the southern end of the Pegu Yomas, there, clothed with dense evergreen forest which, in spite of its nearness to Rangoon, is still the haunt of wild elephants. The Rangoon-Prome line of the Burma railways runs through the district.

INSEIN, the chief town, lies 10 m. N.W. of Rangoon, of which it is now almost a suburb. It has a population (1921) of 14,308, has railway workshops, a Government engineering school and a large gaol.

INSOMNIA, or the inability to sleep adequately, is a common enough symptom in modern life and varies greatly in degree. Our understanding of its underlying causes is often rendered the more difficult because of our lack of knowledge concerning the

exact physiology of normal sleep.

Three varieties of insomnia may be roughly distinguished: the inability to fall asleep at the onset for a variable period; the frequent awakening with incapacity to resume sleep for some time; the waking up at an unduly early hour with no subsequent sleep. Every individual case must be investigated carefully on its own merits, and the physician is frequently taxed to the utmost to combat the symptom on rational and not empirical lines. The responsible causes may have a bodily basis or must be sought in the mind. Among the former must be enumerated the evident factors of pain or discomfort from any cause: shortness of breath, cough, frequency of urination, itching, palpitation. Febrile conditions, high blood-pressure and other circulatory disturbances, toxic states and organic disease of the brain are also liable to be responsible.

In many forms of mental derangement insomnia is a frequent symptom and often heralds its inception. This is specially so in anxiety conditions, where unpleasant dreams may exaggerate the sleeplessness, and here the sufferer may fear to lose consciousness because of these experiences which he cannot control. In neurasthenia and many hysterical states insomnia is likely to be prominent. In such psychoses as manic-depressive insanity, dementia praecox, confusional insanity and general paresis, such a symptom is generally part of the clinical picture.

The advent of insomnia should never be regarded lightly but means should at once be taken to trace its root if possible. The appropriate treatment will depend upon the physical or mental origin. Attacking the symptom only is highly unscientific. Though indiscriminate sedative drugging must be deprecated, the possible harm from the medical administration of hypnotics is much exaggerated. Good sleep thus brought about may cut short a mental illness. In mild cases simple measures may do much while severe insomnia may be highly intractable. The use of suggestion or hypnosis is occasionally beneficial. (C. S. R.)

INSPIRATION is strictly the act of drawing physical breath into the lungs as opposed to "expiration." Metaphorically the term is used generally of analogous mental phenomena; thus we speak of a sudden spontaneous idea as an "inspiration." The term is specially used in theology for the condition of being directly under the divine influence, as the equivalent of the Greek *θεοπνευστία* (2 Timothy iii. 16). Similar in meaning is *ἐνθουσιασμός*, enthusiasm (from *ἐνθουσιάζω* from *ἐνθεός*). Possession by the divine spirit (*πνεῦμα*) was regarded as necessarily accompanied by intense stimulation of the emotions.

The Doctrine of Communion.—The possibility of a human being becoming the habitation and organ of a divinity is generally assumed in the lower religions. In the popular religion of China some of the priests, the *Wu*, claim to be able to take up into their body a god or a spirit, and thereby to give oracles. The Maoris at the initiation of the young men into the tribal mysteries sing a song, called "breath" to the mystic wind by which they believe their god makes his presence known. An Australian woman claimed to have heard the descent of the god as a rushing wind. In some savage tribes blood is drunk to induce the frenzy of inspiration; music and dancing are widely employed for the same purpose. Dionysus, the god of wine in Greece, was also the god of inspiration; and in their orgies the worshippers believed themselves to enter into real union with the deity. In Delphi the Pythia, the priestess who delivered the oracles, was intoxicated by the vapour which rose from a well, through a small hole in the ground. As the oracles were often enigmatic, they were interpreted by a prophet. In Rome the inspiration of Numa was derived from the nymph Egeria; and great value was attached to the books of the Cumaean Sibyl. In Arabia the *kahin* (priest) was recognised as the channel of divine communication. Inspiration may mean only possession by the deity, or it may mean further that the person so possessed becomes the channel through which the deity reveals his word and will. (See J. A. Macculloch's *Comparative Theology*, chap. xv., 1902.)

Prophecy in the Old Testament in its beginnings is similar to the phenomenon in other religions (1 Sam. ix. 8, x. 10-11). The prophesying in which Saul took part probably included violent

ACADEMY, WEARING NATIVE DRESS

movements of the body, inarticulate cries, a state of ecstasy or even frenzy. The phrase "holy spirit" in Acts, as applied to the Apostolic Church, probably indicates a similar state of religious exaltation; it was accompanied by speaking with tongues, inarticulate utterances which needed interpretation (1 Cor. xiv. 27). In every religious revival, when the emotions are deeply stirred, similar phenomena are met with. Such a movement was Montanism in the 3rd century. At the Reformation, while Luther was at the Wartburg, fanaticism broke out, and spread from Wittenberg; prophets went about declaring the revelations which they had received. The Evangelical revival in the 18th century also had its abnormal religious features. The Revival in Scotland in 1860 was marked by one curious feature—the Gospel dance—when in their excitement men and women got up and spun round and round till they were exhausted. Spontaneous praise and prayer marked the revival in Wales in 1905-06.

Prophecy, as represented by the writings of the prophets, arose out of this state of religious exaltation, but left behind many of its features. The function of the prophets was to interpret the course of history as the divine providence for the chosen people Israel, so as to communicate God's Word and Will in judgment or in mercy. They were divinely endowed for this function by their inspiration. While these prophets seem to have continued in the exercise of all their normal faculties, which were stimulated and not suppressed, yet they do claim a distinctive divine activity in their consciousness, and distinguish with confidence their own thoughts from the revealed word. That abnormal psychic states, such as visions and voices, were sometimes experienced is not improbable (see Theodore H. Robinson, *Prophecy and the Prophets*), but the usual prophetic state seems to have been one of withdrawal of attention from the outer world, absorption of interest in the inner life, devout communion and intercession with God, and the divine response in a moral or a spiritual intuition rather than an intellectual ratiocination. Possession by the Spirit in its external manifestations is ascribed to Gideon, Jephthah, Samson, Saul, Elijah; but even when the same language is used of the later prophets, it is probably such an inward state as has just been described which is to be assumed.

A feature inseparable from this later phase of prophecy is *prediction*. For the warning or the encouragement of the people the prophet as Jehovah's messenger declares what He is about to do. Thus the fall of Samaria in 722 B.C., the deliverance of Jerusalem in 701, the overthrow of the kingdom of Judah in 586, the return from exile in 537 were all heralded by prophecy. This prediction was no shrewd political conjecture, but an application to existing conditions of the permanent laws of God's government. The abnormal phenomena of inspiration, the presence and operation of the Holy Spirit, in the Apostolic Church, have already been noticed.

The New Testament.—While Paul does not deny nor depreciate these charisms, as tongues, miracles, etc., he commends as the more excellent way the Christian life in faith, hope and love (1 Cor. xii. 31). The New Testament represents the Christian life as an inspired life. It is living communion with Christ, and therefore constant possession of the Holy Spirit. Every Christian, in the measure in which he has become a new creature in Christ, is a prophet, because he knows by the enlightening of God's Spirit "what is the good and acceptable and perfect will of God" (Romans xii. 2). An occasional state of divine possession in the other religions becomes in the prophets of Israel a permanent endowment for a few select agents of God's revelation; but when that revelation is consummated in Christ, inspiration becomes the universal privilege of all believers.

Apologetics.—While there is much superstition in the view of inspiration found in many religions, and much imposture in the claims to the possession of it, yet it would be illogical to conclude that this feature of religion is altogether human error and not at all divine truth. Man's knowledge of God is conditional, and therefore limited by his knowledge of the world and himself, and has accordingly the same imperfection. The reality of a divine communion and communication with man is not to be denied because its nature has been imperfectly apprehended. We must

estimate the worth of inspiration by the higher and not the lower stages, by the vision of an Isaiah or the consecration of a Paul; but at the same time we must be prepared to recognise its lowly beginnings.

In dealing with the inspiration of the Bible, to which the use of the term has in the Christian Church been largely restricted, it is important to remember that inspiration is primarily personal; and that it assumes varied forms and allows varying degrees.

Other religions besides Christianity possess their sacred scriptures and the claim of inspiration is advanced for some of them, as by Hinduism for the *S'ruti* (hearing) writings as distinguished from the *Smriti* (recollection), Zoroastrianism for the Zend-Avesta, Islam for the Koran. But Buddhism advances no such claim for its *Tripitaka* (three baskets), nor Confucianism for its classics.

Exegesis.—The Pentateuch was accepted as authoritative law by the Jewish Church in 444 B.C. About two centuries later the Prophets (including the histories as well as the prophetic writings proper) were also acknowledged as sacred scriptures, although of inferior authority to the Law. In the century before the Christian era the Writings, including Psalms and Proverbs, were included in the Canon. Palestinian and Hellenistic Judaism disagreed about the recognition of the books now known as the Apocrypha. The writers of the New Testament use the Old Testament as holy scriptures, as an authoritative declaration of the mind and will of God; but the inaccuracy of many of the quotations, together with the use of the Greek translation as well as the original Hebrew, forbid our ascribing to them any theory of verbal inspiration. By the middle of the 2nd century the four Gospels were probably accepted as trustworthy records of the life of Jesus. The Epistles were accepted as authoritative in virtue of apostolic authorship. By the end of the 3rd century the use and approval of the churches had established the present canon.

The doctrine of the inspiration of these writings in the Jewish and Christian Church now claims attention. Inspiration is first of all ascribed to persons to account for abnormal states, or exceptional powers and gifts; in this doctrine it is transferred to writings, and its effects in securing for these inerrancy, authority, etc., are discussed with little regard for the psychic state of the writers.

The New Testament affirms the inspirations of the Old Testament (Matt. i. 22, xv. 4, Mark xii. 36, Acts i. 16, Romans iii. 2, ix. 25, Heb. i. 1, 1 Peter iv. 11). The term is used in regard to the Scriptures in 2 Timothy iii. 16. The Spirit of Christ is said to have been in the prophets (1 Peter i. 11); and it is affirmed that "no prophecy ever came by the will of man; but men spake from God, being moved by the Holy Spirit" (2 Peter i. 21). The constant use of the Old Testament in the New confirms this doctrine of inspiration.

Contemporary Jewish thought, as expressed by Philo, Josephus, and the Talmud according to Weber, was in agreement with this view of the Old Testament. But the nature of this inspiration must be more closely defined, and hence have arisen a number of theories of inspiration which can be only briefly mentioned. The theory of *verbal inspiration*, which was held by Plato, Philo, the Apologists, the Fathers, and the Protestant Scholastics, ignores the data which the Bible itself offers. The theory of *dynamic influence or degrees of inspiration* recognises that the human personality is not entirely suppressed by the direction and control of the Spirit; but it does not offer us any sure guidance in discriminating the human and the divine factor, and in estimating the value of the contents of the Bible. The theory of *essential inspiration* in claiming inspiration only in matters of doctrine and conduct (anticipated in Aquinas' distinction of *direct* and *indirect* inspiration, and favoured by Erasmus, Hugo Grotius, Baxter, Paley, etc.) betrays a too intellectualist standpoint in the emphasis it lays on correctness in theology and ethics, and ignores the progressive character of revelation.

Protestantism.—The theory of the Reformers (though not of their successors, the Protestant scholastics)—might be called that of *vital inspiration*, as its emphasis is on religious and moral life rather than on knowledge. While giving to the Scriptures supreme authority in all matters of faith and doctrine, the Reformers laid

stress on the use of the Bible for edification; it was for them primarily a means of grace for awakening and nourishing the new life in the hearts of God's people. By the enlightening work of the Spirit of God the Word of God is discovered in the Scriptures: it is the *testimonium Spiritus Sancti* in the soul of the Christian that makes the Bible the power and wisdom of God unto salvation. By thus laying stress on this redemptive purpose of the divine revelation, the Reformers were delivered from the bondage of the letter of Scripture, and could face questions of date and authorship of the writings frankly and boldly. Hence a pioneer of the higher criticism in Great Britain, W. Robertson Smith, was able to appeal to this Reformation doctrine (quoted in Denney's *Studies in Theology*, p. 205). The Reformers' application of this theory to the Bible was necessarily conditioned by the knowledge of their age; but it is a theory wide enough to leave room for our growing modern knowledge of the Bible.

Résumé.—Briefly stated, these are the conclusions which our modern knowledge allows. (1) Inspiration, or the presence and influence of the Divine Spirit in the soul of man, cannot be limited to the writers of the Scriptures; but, comparing the Bible with the other sacred literature of the world, its religious and moral superiority cannot be denied, and we may, therefore, claim for it as a whole a fuller inspiration. (2) As different writings in the Bible have more or less important functions in the progressive divine revelation, we may distinguish degrees of inspiration. (3) This inspiration is primarily personal, an inward enlightening and quickening, both religious and moral, of the writer, finding an expression conditioned by his individual characteristics in his writing. (4) The purpose of inspiration is practical; the inspired men are used of God to give guidance in belief and duty by declaring the word and will of God as bearing on human life. (5) As revelation is progressive, inspiration does not exclude defects in doctrine and practice in the earlier stages and their correction in the later stages of development. (6) As the progressive revelation culminates in Christ, so He possesses fullest inspiration; and it varies in others according to the closeness of their contact, and intimacy of their communion with Him. (7) As the primary function of Christ is redemptive, so the inspiration of the Bible is directed to make men "wise unto salvation." (8) It is the presence and influence in the souls of men of the same Spirit of God as inspired the Scriptures which makes the Bible effective as a means of grace; and only those who yield themselves to the Spirit of God have the witness in themselves that the Bible conveys to them the truth and the grace of God.

INSTALLATION, the action of installing or formally placing some one in occupation of an office or place. The word is used of the ceremonial induction of an ecclesiastic, such as a canon or prebendary, to his stall in his cathedral choir. Similarly knights of an order of chivalry are ceremonially led to their stalls in the chapel of their order.

INSTALMENT PURCHASE, in the law of contract, a form of purchase of goods on a system of extended credit. Originally applied to the sale of the more expensive kinds of goods, such as pianos and articles of furniture, the instalment system has now been extended to almost every description. The agreement is usually in writing, with a stipulation that the payments to purchase shall be by weekly, monthly or other instalments. The agreement is virtually one to purchase, but in order that the vendor may be able to recover the goods at any time on non-payment of an instalment, it is treated as an agreement to let and hire, with a provision that when the last instalment has been paid the goods shall become the property of the hirer. A clause provides that in case of default of any instalment, or breach of any part of the agreement, all previous payments shall be forfeited to the lender, who can take

possession of the goods. Such agreements, therefore, do not pass the property in the goods, until all the instalments have been paid. But the terms of the agreement may sometimes purposely obscure the nature of the transaction between the parties, where, for example, the instalment purchase is merely to create a security for money. In such a case a judge will look to the true nature of the transaction. If it is not a real letting and hiring, the agreement will require registration under the Bills of Sale acts. If the agreement contains words to the effect that a person has "bought or agreed to buy" goods, the transaction comes under the Factors Act, 1889, and the person in possession of the goods may dispose of them and give a good title (see FACTOR). The doctrine of reputed ownership, by which a bankrupt is deemed the reputed owner of goods in his apparent possession, has been somewhat modified by trade customs, in accordance with which property is frequently let out on the instalment system (see BANKRUPTCY).

In the principal British dominions, such as Canada and Australia, real property is frequently sold for payment on the instalment system, usually during three years, some particulars of which will be found in Burge's *Foreign and Colonial Laws*, vol. iv. part ii. Instalment purchase is also the system followed by the building societies (*q.v.*), under which their members buy houses for themselves.

See also **INSTALMENT SELLING**.

(W. A. B.)

United States.—Instalment purchase in the United States takes either the form already described above, and known as the conditional sale, or the form of a sale outright with chattel mortgage (see **BILL OF SALE**) for the unpaid portion of the price. An apparent lease which in substance amounts to a conditional sale is almost universally treated as the latter, regardless of its form.

The fact that the goods are in full use of the buyer and hence appear to be his, opens the possibility of his creditors being misled by his apparent ownership, and even more the possibility that *bona fide* purchasers of the goods from him may be misled, if the secret rights of the seller are given full force. These considerations have led in more than half the States to legislation under which a contract of conditional sale fails to preserve the seller's rights as against *bona fide* purchasers from the buyer, or as against described classes of the buyer's creditors (including his trustee in bankruptcy) unless the contract is publicly filed or recorded in much the same manner everywhere required for a chattel mortgage. Where such filing is not required, sellers commonly use the conditional sale in the instalment purchase, to save the expense of filing, as also to avoid the publicity of filing, which generally is objectionable to the buyer as reflecting on his credit. On the other hand, wherever such filing is required—except in the nine States which have adopted the Uniform Conditional Sales Act—there is much to be said in favour of using the chattel mortgage back as the lender's security. For there are disadvantages in the conditional sale when it comes to realization on the security. If a chattel mortgagee retakes the goods and forecloses on default, he is still entitled to recover at law any difference between the amount of the unpaid debt and the value of the goods, or the amount for which they sell on foreclosure. But, except under the Uniform Act, a conditional seller must elect between retaking the goods and recovering the unpaid portion of the price; both he cannot do, and the retaking of used goods often results in a loss to him. On the other hand, under the conditional sale the seller may in a very favourable case stand to win, since he can keep as forfeited all that has been paid, even though his resale of recaptured goods should result in a profit. In the case of a chattel mortgage, he would then have to pay over the difference to the defaulting buyer (mortgagor); and such is the vastly preferable rule for the conditional sale, as well, as evidenced by the Uniform Act.

In the case of street cars and railroad rolling stock, instalment purchase has been introduced to permit specific new financing to companies whose credit standing has somewhat suffered, and whose properties were already covered by a blanket mortgage framed to include after-acquired chattels. The buyer-company's interest, and hence the blanket mortgagee's, is held to be subordinate to that of the instalment seller, whether the form be con-

ditional sale, purchase money mortgage, or the peculiar Pennsylvania "bailment-lease." Hence "equipment trust" securities can be marketed by a company whose new mortgage bonds cannot; since, too, the equipment in case of default can be removed and sold irrespective of the possible unprofitable location or condition of the road itself.

Land and houses, especially in the case of subdivision development, are often sold on an instalment basis. In that situation radically different rules of law apply; there is no possibility, for instance, of resale by the buyer to a *bona fide* purchaser; forfeiture on default of what the buyer has paid in is almost universal, yet often subject to mitigating periods of grace by virtue of liberal construction of the contract.

See Bogert's *Commentaries on Conditional Sales* (1924); W. A. Estrich, *Law of Instalment Sales of Goods* (1926); K. Duncan, *Equipment Obligation* (1924); E. R. A. Seligman, *The Economics of Instalment Selling* (1927). (K. N. L.)

INSTALMENT SELLING, a system of retail trading which is in essence an extension of credit to purchasers, under some form of contract by which the purchaser agrees to make partial payments at stated intervals over a period of weeks, months or even years. In this article a résumé of American developments will be given first. (X.)

I. IN THE UNITED STATES

In the United States real estate instalment selling is handled mainly through building and loan associations. High-grade furniture houses were the first business houses to make use of instalment selling in the United States. They introduced it early in the 19th century. Soon this method was extended to the marketing of many commodities, among the most important being books, sewing machines, pianos, gramophones, stoves, washing machines, automobiles, vacuum cleaners, clothing, jewellery and radios.

Although instalment selling was first confined to the marketing of high-grade commodities, it is at present used by merchants who sell practically all classes of goods. A certain social stigma came to be attached to the purchase of goods on the instalment plan, especially when it came into use by firms who handled low-grade goods and used questionable methods of marketing their products. Furthermore, there has always been a prejudice against the use of bank credit to finance consumers' purchases. The belief, which has been fostered by economists, has been that bank credit should be confined to the promotion of production, where there would be an increased value created as a result of the extension of this credit. If a person did not have sufficient funds to purchase commodities for consumption, the feeling was that he should go without them until such time as he could afford to purchase them out of accumulated savings. This antipathy was probably one of the causes of the various refinements in names which have been given to instalment selling, such as "deferred payment plan," "purchasing out of income" and "budgeting plan."

A distinction should be made between two broad classes of goods which are sold under instalment plans: consumption and production goods. In many cases it is difficult to determine into which class a sale falls, but the main point is that there is little or no criticism heard of selling production goods on instalment plans, while there is much criticism and discussion as to the justification of the application of these same methods of marketing to consumption goods. Purchases of railway equipment through the use of railway equipment bonds has been an accepted method of financing the acquisition of producers' capital. Payments are made on these bonds over a period of ten years under the same type of plan and contract as is used in instalment sales of consumers' goods. These goods are considered a sound investment and in many cases have shown themselves more secure than mortgage bonds.

Larger growth of instalment selling has taken place in the marketing of consumption goods and the increase is primarily the result of the development of the use of this form of credit in the automobile industry. Conservative estimates show that about 70% of all automobiles sold since 1925 have been financed through instalment plans. The most recent estimate made of the amount

of instalment sales is \$4,500,000,000 out of a total annual sale of \$38,000,000,000.

The mainspring of the mechanism of instalment selling is the finance company of which there are two types: the independent company and the subsidiary company which is organized by the parent company for the sole purpose of financing sales of its products. An example of the first type is the Commercial Credit company of Baltimore, incorporated in 1910, while the General Motors Acceptance Corporation is the outstanding example of a subsidiary. The independent companies finance sales of a variety of commodities, and are divided into a number of different departments which handle the financing of particular groups of commodities. As a rule, the independent companies use what is termed the non-recourse plan, while the subsidiaries use the recourse plan. Under the recourse plan the dealer signs the instalment paper and thus assumes a liability for the failure of the customer to live up to the terms of the contract. In case of default by the customer, the dealer resumes possession of the article and must again dispose of it to recover the remainder of money still owed to him. Under the non-recourse plan the dealer does not assume any obligation, and in case of default the finance company repossesses the article and offers it for sale. Both types of finance companies furnish credit for wholesale as well as retail sales.

As the most important part of instalment selling is devoted to automobiles, this feature of the development should be considered in more detail. Instalment selling of automobiles did not come into existence until after 1910. It was about that time that dealers in California are said to have originated it. Growth was slow in the industry for the first few years, and the sales were financed by the dealers themselves without assistance from finance companies. There were a few scattered examples of firms which purchased automobile paper beginning about 1913, but this was uncommon. Rapid growth started after the World War. The amount paid at the time of purchase varies from about 25% to 40% of the purchase price of the car. The length of time covered by the subsequent payments is usually between 6 and 18 months. Ordinarily, a larger down payment and a shorter elapsed time is used in the case of second-hand cars. In the sale of new cars the best practice calls for a minimum down payment of one-third the purchase price and the length of time for subsequent payments to be spread over a period of not more than 12 months. However, these terms are not followed closely, and there are many exceptions. It is found that the number of repossessions necessary and the losses of finance companies increase alarmingly when the terms are made more lenient. The terms of all instalment paper should be drawn up so as to give the purchaser sufficient equity in the commodity to make it his interest to keep up the remaining payments. Fire and theft insurance is paid by the purchaser, and the rate is usually high enough so that it will cover the risk of conversion, that is, the chance that the purchaser may steal the car before all his payments are made.

The most widely used form of contract in instalment selling is the conditional sale, which is signed by the purchaser. It contains three distinctive features: (1) title remains in the seller, (2) possession is generally held by the purchaser, and (3) title passes to the purchaser on complying with the conditions of the sale. If the buyer fails to meet his payments the seller may repossess, and the seller is not compelled to refund any of the payments already made unless there is legislation to this effect in the State where the sale is made. In event of such legislation, the seller may be required to return to the purchaser any amount he receives on resale of the article above the amount which remains due from the purchaser and his costs. In those States where a conditional sale is not legal, a lease plan or chattel mortgage is used to finance instalment sales. In this case, the purchaser is considered to have leased the article and pays rent for the length of time covered by his payments (see *infra*). There is no fundamental difference to the purchaser in the cost of these various plans.

It is difficult to estimate the pure interest rate which the purchaser pays for the money he borrows in instalment buying, because of the fact that the costs of financing are included in the payments made, in addition to the insurance charge, and the loan

is amortized in the periodic payments. In general the cost of the credit varies between 10 and 30%.

In order to secure funds to finance this paper, finance companies resort to the sale of short-term paper to banks. They keep a certain amount of instalment paper in a selected bank under a deed of trust, and against this collateral, they issue short-term paper which is offered to banks for short-term investments. The losses of finance companies have been relatively small, some reporting losses through repossession of about $\frac{1}{2}$ of 1%. Large losses have, however, occurred where the terms or the credit departments have become too lax.

Undoubtedly, the volume of production of certain groups of articles has been increased through the development of instalment selling. This increase has brought about lower costs, so that in many cases the consumer has benefited. But against the gain we must consider the cost of the necessary credit to the consumer. It is probable that production of goods which have not lent themselves so readily to instalment has suffered in consequence, with the result that the articles which go to make up the various standards of living have changed in nature and quantity. One of the main drawbacks to the consumer is that he has not been able to budget his income properly. He does not know from experience what margin of safety he should keep. For this reason it is imperative that there should be improvements in the credit investigation departments of finance companies.

Instalment selling has undoubtedly come to stay, and may be expected to improve in the future with further experience. At the present time, the United States has abundant credit which is available at a low rate of interest. Should the interest rate go up with an increased demand for credit in other fields, the cost of instalment financing would have to increase. At the same time another fact should be noted; the country has not been through a severe crisis since instalment selling has become so important. It remains to be seen whether it is possible for the consumer to resume his buying as soon after a crisis as has been the case in the past. If his return to the market is delayed because of obligations which he has assumed already and which must be met before he can become part of the effective demand for new goods, then the recovery of business after a crisis will certainly be delayed. (B. G.)

II. INSTALMENT SELLING IN GREAT BRITAIN

Instalment selling has proved an invaluable aid to certain young and some old British industries since the World War. It is unlikely that the motor, wireless, electrical equipment, pianoforte or furniture industries would be in their present healthy state, had not instalment selling come to their assistance. For long years past, the British building societies have fostered the wise plan of buying houses on the instalment system and their growth has been remarkable. (See BUILDING SOCIETIES.)

Estimates of Extent.—How far instalment selling is responsible for sales in the wide range of industries it serves, no one can estimate. British industries collect few data for such a computation. The Hire Purchase Traders' association has estimated that 4,000,000 instalment agreements are entered into annually, and that 16,000,000 such agreements were in 1928 in force. The association also estimates that instalment agreements account for 50% of motor-car sales; for 50% of furniture sales; and for 10% of jewellery sales in Great Britain. These figures are given with reserve; they are rough estimates and nothing more. It is clear, however, that a large percentage of the farm implement, factory equipment, office machinery, bicycle trades and a small percentage of the clothing, bible and bookselling trades is done on the instalment basis.

Certain other services seem to be suited to the instalment method of selling. One of these is insurance, which has been sold to the British working classes by weekly payments for half a century or more. One company is selling life policies to the middle classes on the monthly payment system, while another has announced its intention of following suit. Travel is being sold in the same way. One of the British railway groups is to sell holiday tickets on instalments, collecting sixpence or a shilling weekly. The British income tax is collected in instalments.

One is often asked the question: by how much will instalment selling increase sales? The answer depends on the nature of the article, the type of public appealed to, the terms offered, the state of competition and other factors. A specific case will illustrate the possibilities of the method.

The Remington Typewriter Company offered their portable typewriters on the instalment system in April 1925, their terms being an initial payment of £2 2s., followed by 11 monthly payments of £1 1s. Taking the sales for the six months preceding this offer at the index figure of 100 per month, it was found that the index of sales had increased in Oct. 1925 to 210, in November to 269, and in December to 325. In eight months instalment selling had increased the sale of portable typewriters by over 200% while the newspaper advertising for the eight months was only about 5% above that for the preceding six months.

Tempting the Consumer.—The question has been raised whether the consumer may be tempted by instalment selling to buy beyond his means. There are undoubtedly instances in which working-class families become indebted for furniture, a gramophone, clothing, etc., at one and the same time. In such cases the instalment payments due on a given date may exceed the wages available. Is not this the genesis of a grave social evil?

The answer to that question is that experience shows that the percentage of bad debts incurred in instalment selling in Great Britain is astonishingly small. The members of the Hire Purchase Traders' association have for many years past kept their bad debts below 2%; many concerns keep them well below 1%.

The social reformer is apt to assume that the temptation to reckless buying is greatest to the poorest. It may be so, but the fact remains that the *ability to budget expenditure*—and here lies the crux of the question—seems to vary in proportion to the shallowness, and not the depth, of the housewife's purse. The Frenchwoman buys more carefully and expertly than the Englishwoman, while the latter makes money go farther than the American housewife. It is probable that the danger of instalment selling to the working-classes in Great Britain has been exaggerated.

On the other hand, it cannot be too clearly recognized that with instalment selling a new situation has arisen. The balance of power as between salesman and customer has been upset. While Mrs. Brown may be quite competent to deal with her local shopkeeper, she may not have the skill to cope successfully with the travelling salesman or with the salesman of a department store. A superior technique of salesmanship may be opposed to an inferior technique of buying. In such circumstances, there may be cases in which the housewife is tempted to purchase beyond her means.

Until 1928, instalment selling was managed on a more conservative basis in Great Britain than in America. While the American banks only attempted to set standards of practice in 1925, the long experience of British business and the conservative policy of the British banks have secured a cautious policy; factors of safety have been operative.

At the same time, it has to be admitted that one or two British industries are now leaving these standards of practice behind them. Certain firms for instance are now working on the "no deposit, long term agreement" system. As most of the companies concerned are large and possess corresponding financial resources, there need be no need for anxiety in their interests. Inevitably both they and their customers must pay a little more for the facilities offered: how much, is a matter of accountancy.

Facilities for Instalment Trade.—There are now several British financing companies ready to take over the small trader's accounts and to give his customers instalment credit. This accommodation will enable the small retailer increasingly to compete with the large concerns. In some cases these financing companies allow the retailer himself to collect accounts, so that he does not lose contact with his customers.

In 1928 the facilities available for the small trader to give his customers instalment terms were multiplying in other directions. A number of manufacturers were prepared to finance the instalment sales of their dealers on a reasonable basis; a few whole-

salers in certain lines offered the same facilities; and the banks themselves ceased to protest that they would not finance instalment sales. This change of attitude was sponsored by the Midland Bank in its *Bulletin* (Feb.-March 1928) in the following terms:—

The banks, in the ordinary course of providing direct accommodation to their own customers, probably provide a considerable part of the funds required for carrying on hire-purchase business. This does not imply that the banks actually lend specifically for hire-purchase trade, but in the ordinary course of operation of their overdraft facilities, substantial sums, though unidentifiable in detail, are probably lent for this purpose. Similarly, the banks are called upon from time to time to lend large amounts to finance the operations of manufacturers, some of whom may be producing partly or wholly to meet the hire-purchase demand. In these cases again the banks are indirectly financing this particular type of business. Consequently it would be wrong to say that the banks do not grant accommodation for hire-purchase business, merely because they do not hold themselves out to participate in exactly the same way as in America.

How much does instalment credit cost? The financing company may charge 5% to 8% on each transaction for 12 months' accommodation. Obviously, the actual rate of interest paid is 10% to 16%, since the average amount on loan is only half of the total. It must be remembered, too, that the retailer is normally charging his customer from 5% to 8% for the credit given so that the net cost to the retailer is trifling. It will be clear, however, that the instalment method of selling entails the use of greater capital in relation to turnover than cash selling.

(C. CH.)

INSTERBURG, a town in the province of East Prussia, at the point where Angerapp and Inster join to form the Pregel, 57 m. E. of Königsberg by the railway to Eydtkuhnen, and at the junction of lines to Memel and Allenstein. Pop. (1925) 39,390. Insterburg, the "burg" on the Inster, was founded in the 14th century by the knights of the Teutonic order. Having passed to the margraves of Brandenburg, the village which had sprung up round the castle received civic privileges in 1583. During the next century it prospered greatly, partly owing to the settlement in it of several Scottish trading families. In 1679 it was besieged by the Swedes; in 1690 it suffered severely from a fire; and in 1710-11 from pestilence. The town church is celebrated for its fine wood carvings. Besides flax-spinning and iron-founding, Insterburg has manufactures of machinery, cement, leather and beer, along with a considerable trade in cereals and wood, while horse-breeding is extensively carried on in the neighbourhood.

INSTINCT: see ANIMAL BEHAVIOUR; PSYCHOLOGY; COMPARATIVE PSYCHOLOGY.

INSTINCT IN MAN. The current views regarding human instinct at the beginning of the modern period are very well represented in Lord Herbert of Cherbury's *De Veritate* ("On Truth"), published in 1625. In enumerating the human faculties Lord Herbert starts with "Natural Instinct." This has two aspects. On the one hand, it is the source of the motives which urge both men and animals irrationally to seek to preserve their lives and to secure happiness. On the other hand, it furnishes certain innate principles of knowledge—"common notions," Lord Herbert called them. The prevailing usage of the word "instinct" up to the middle of the 19th century is fairly well represented by Lord Herbert's *Instinctus Naturalis*. In the discussion of human instinct, however, the first aspect was more and more emphasized. "Natural propensity," or "natural inclination" was essentially the meaning of the word, when applied to the human being.

New Meaning of Instinct.—During the 19th century, and especially after Darwin, the problem of instinct began to be approached from a new standpoint. The direction of approach was now from the side of animal behaviour, in place of human conduct. The word "instinct" was taken as designating forms of behaviour which were not acquired by an animal through experience and learning, but provided for congenitally in the animal's structure, and manifested on the first occasion of performance, if not perfectly, at least adequately to secure the survival of the individual and the continuance of the species. When this meaning was carried over to the case of the human being, the stage was set for the acute controversy regarding Instinct in Man, which has characterized the first three decades of the 20th century. The

two parties in this controversy are, on the one side, those who adhere more or less firmly to the original meaning of the word "instinct" as "natural impulse" or "urge," and, on the other side, those who, taking their departure from the complex types of instinctive behaviour characteristic of some of the lower forms of life, take the word as meaning "congenitally organized patterns of behaviour." On the whole the line of division between these opposing views corresponds in psychology to the line between the introspectionist and the behaviourist, and in general philosophy to the line between the finalist and the mechanist.

The controversy has largely centred round the problem of the relation of Instinct to Intelligence or to Habit. As far as the science of psychology is concerned the opposing standpoints can be reconciled. If we define psychology as the science which studies the behaviour of the living organism, and seeks to understand and interpret that behaviour in terms of the inner life of thought and feeling, it is possible to preserve the traditional sense both of "psychology" and of "instinct," and at the same time to cover the new fields in both cases. There is no opposition between Instinct and Intelligence, provided we consider both at the same level in the animal scale. Low down the scale there is almost complete provision in the structure of the organism at birth for all actions necessary to preserve its own life, and to secure the continuance of the species. The part left for intelligence to play is insignificant, and we have no evidence of the presence of any high degree of intelligence. Higher up the scale the congenital provision for necessary actions is incomplete, and a special supplementing through individual learning is required. Intelligence has a more important rôle to play, and the evidence for the possession of the necessary intelligence begins to accumulate. At the top of the animal scale the congenital provision in the structure of the organism for those actions which are necessary to maintain life is incomplete and fragmentary in the highest degree, so much so that there may well be doubts in some cases whether it exists at all. At this level the part which intelligence must play becomes very important, and the evidence for a high degree of intelligence becomes overwhelming. From the bottom to the top of the scale, however, there is evidence of the presence of a powerful impulsion from within, urging the organism towards actions, guided by such intelligence as there is, which tend to serve great biological ends. It was this impulsion, to which the name "instinct" was originally given, and it is this impulsion upon which we must concentrate attention, if we would understand human instinct.

Instinct and Emotion.—The chief human instincts—regarding instincts from this "impulsion" point of view—are those associated with fundamental human emotions, like fear, anger, sex love, parental love, etc. The relation of Emotion to Instinct has been another fruitful source of controversy. Early and modern writers are both agreed that there is some close relation. By the early writers the relation was more or less tacitly assumed. William James, on the other hand, in more recent times, explicitly asserted it. It was left to William McDougall, however, to define the relation more precisely, and the controversies have centred mainly round McDougall's work. According to his view each instinct has associated with it a characteristic emotion, which is always the stable and peculiar mark of the activity of that instinct. This view has been challenged by A. F. Shand, who maintains that McDougall has reversed the actual relationship, and that the activity of an instinct is rather to be regarded as a constituent element in the activity of an emotional system. J. Drever has also criticized McDougall on the ground that he has over-simplified the situation, and that emotional excitement always exhibits a bipolarity characteristic of the whole life of feeling, so that, even if we admit that emotional excitement always accompanies instinctive activity, we must assume that two emotions of opposite polarities—"joy" and "sorrow" emotions—are involved in the case of each of the instincts. Drever, however, refuses to admit that all instinctive activity necessarily involves emotional excitement, holding that emotion is experienced only when the instinctive impulse is facilitated or impeded in the attainment of its end, and that some instincts, like imitation and play, have no characteristic emotion at all associated with them. Larguier des Bancelles, again,

holds that emotional excitement represents in essence a disorder of instinct.

Enumeration and Classification of Human Instincts.—McDougall's teaching in its general features has been widely accepted, more particularly as regards the enumeration of the human instincts. His list includes: the instincts of fright or escape, pugnacity, repulsion, curiosity, self-display, submission, sex, acquisitiveness, the parental instinct, the gregarious instinct, the hunting instinct. To these must be added: imitation, play, certain simple instincts showing themselves in early childhood, the natural appetites, and possibly the wandering instinct. This enumeration is based on the view of Instinct as natural impulse. Writers who approach Instinct from the behaviour side, like Thorndike, for example, enumerate many more, while the psycho-analysts, though making extensive use of the notion of Instinct, rarely attempt any enumeration at all. S. Freud, the leader of the psycho-analysts, employs the term "wish" in a sense which is practically equivalent to "impulse" or "instinct."

The classification of human instincts presents considerable difficulty. The most popular classification is probably into ego instincts, sex instincts, and herd instincts. This classification is based on the Freudian psychology, but it is unfortunately biological rather than psychological. At least two psychological classifications have been suggested: into instincts of attraction, repulsion and aggression, and, harking back to Plato, into appetitive and reactive instincts, and under each head into general and specific. W. H. R. Rivers, who may be said to mediate between the views of the psycho-analysts and those of McDougall, has suggested a classification of an entirely new basis. He contends that the activity of some instincts shows an "all-or-none" character, a want of control and discrimination, while in other cases there is a grading of intensity of action, and a delicate adjustment of activity to end. The two types might therefore be called "protopathic" and "epicritic," respectively. This distinction seems equivalent to a distinction between presence and absence of emotion.

For instinct in animals see ANIMAL BEHAVIOUR.

INSTITUTE OF THE CHRISTIAN BROTHERS, or, more fully, "Institute of the Brothers of the Christian Schools," a religious fraternity founded at Reims in 1680, and formally organized in 1683, by the priest, Jean Baptiste de la Salle, for the purpose of affording a free education, especially in religion, to the children of the poor. Though not officially connected with the Jesuits, their organization and discipline are very similar; and their work is now carried on in all parts of the world.

See J. B. Blain, *La vie du vénérable J. B. de la Salle* (1887); and P. Joseph, art. "Institute of the Brothers of the Christian Schools" in the *Catholic Encyclopaedia* (with many references).

INSTRUMENT, that which can be used as a means to an end, hence a mechanical contrivance, implement or tool; the word is more particularly applied to the implements of applied science, in mathematics, surgery, surveying, etc., while those of the handicrafts are generally known as "tools." A specific use of the term is for the various contrivances used to produce musical sounds, "musical instruments."

In law an "instrument" is any formal or written document by which expression is given to a legal act or agreement. This is a classical use of the Lat. *instrumentum*, a document, record. The term may be used in a wide sense, as a mere writing, meant only to form a record, or in a particular sense with reference to certain statutes. For example, the Stamp Act 1891 defines an instrument as an expression including every written document; for the purposes of the Forgery Act 1861 a post-office telegram accepting a wager has been defined as an instrument.

INSTRUMENTATION is the aspect of music which deals with timbre, and with the technical possibilities and characters of

instruments and voices. The treatment of the orchestra has for the last hundred years been the most popular branch of the art. Hence the vogue of the narrow term "orchestration." The colloquial word "scoring" is the only adequate name for an art that ought to include all other aspects of timbre and performance, such as chamber-music (*q.v.*), pianoforte writing and organ registration.

Method of Study.—The first requisite for good scoring is an imagination exercised by training. Rules are not enough; and neither is mere practical experience. Schumann's scoring grew worse as experience discouraged him; and a student who masters good rules without training his imagination merely protects himself from learning by experience. Many musicians who ought to know better are doing serious mischief by denying the possibility of arm-chair score-reading. Exaggerated claims are harmless for they are nearer to the truth of what an accumulation of study can achieve. The common-sense of the matter is obviously this: the arm-chair reader can vividly imagine effects that he has heard; he can recognise similar effects when he sees them in a score that is new to him; and so with effort and practice he can realise the effect of known sounds in new combinations. The complexity of the combinations has, in reason, little to do with the difficulties of imagination; and familiarity with the type of music is always a paramount factor.

William Wallace, in *The Threshold of Music*, seems to believe that modern progress in orchestration has produced new cerebral powers. This is a fallacy: listeners or conductors who have become familiar with Richard Strauss's orchestration will vividly imagine the sounds of a page of the master's latest and fullest scoring long before scrutiny has shown more than the main entries and the general type of colouring. But such readers may get nothing but abstract grammatical propositions from a page of Palestrina if they have never heard pure polyphony sung without accompaniment in a vaulted building. The music of each great period has its own proper scoring which sounds well under its proper conditions. The student should take opportunities of hearing each kind of music well produced; and he should multiply his experience by reading the scores of all periods, besides those of his own day. An imagination thus trained is obviously useful to conductors. It is not less useful to composers, for it is no mere antiquarian lore by a widely generalised capacity to imagine correctly all kinds of significant musical sounds. Its possessor will never produce the woolly scoring of the unimaginative composer who goes by rule; and if he makes errors of calculation these will be remediable as errors of imagination are not.

Rules are useful in preventing errors of calculation. The only extant treatise on instrumentation that gives correct rules is the posthumous work of Rimsky-Korsakov. Starting with the proposition that good scoring is good part-writing, this brilliant and fantastic Russian composer lays down surprisingly severe rules for combining good part-writing with well-balanced orchestral values. At first it seems incredible that any free art could live on such terms; yet the marvellous purity of Mozart's orchestration supports Rimsky-Korsakov's system in an art a century earlier and far more complex. For there is less wonder that Rimsky-Korsakov's colouring should be pure since his ideas never overlap, and his hundreds of illustrations from his own works consist (except for a few scraps of recitative) exclusively of 2-bar or 4-bar phrases that repeat themselves. We shall not learn Mozart's art from this, and rules will not endow us with Rimsky-Korsakov's imagination. Nor was that imagination equal to distinguishing blunders from subtleties in the score of his friend Moussorgsky's *Boris Godounov*. Much less, then, is it to be trusted when he dismisses Beethoven's orchestration with the remark that the execution of Beethoven's ideas is far inferior to their conception. This really means that the narrow cross-section of Beethoven's ideas that comes within the aesthetic range of Russian ballet-music could have been scored more easily and brilliantly by a Russian composer in 1890. Apart from this, Beethoven is doubtless not infallible. But perkiness starves the imagination.

Pure 16th Century Polyphony.—In the article HARMONY (*q.v.*) the grammar of pure polyphony is shown to be equivalent

to the art of vocal scoring. A modern choir soon learns the truth of the 16th century rules when it faces the task of unaccompanied rehearsal. The old rules secure singability as well as euphony. But they also leave the composer's imagination free for many subtleties. Our stereotyped full chorus of soprano, alto, tenor and bass is roughly that of the 16th century, though we have forgotten the ways of the genuine boy-alto who delights in manly growls down to D and becomes shy above A in the next octave. The 16th century knew no other alto, and Palestrina has 17 ways of grouping 4 parts and 12 different ways for 3 parts, besides equally various 5-part and 6-part grouping. In 8-part works for double choir the two choirs are often contrasted, as in Palestrina's motet and mass *Hodie Christus natus est*, where the second choir, led by the altos, makes a terrestrial antiphony to a choir of angels.

The infinite subtleties of 16th century part-writing are beyond the scope of this article and very remote from the experiences of any instrumental music. But every conductor and every composer may learn much from Palestrina's and Lasso's devices of producing by part-crossing beautiful progressions that would be crude if the planes of tone were not kept distinct. In all later periods the distinction of planes of tone is a fundamental principle. In the 16th century it enters into these delicate intricacies, and appears more obviously in the rule formulated by the first composers for double and triple choirs, viz., that the harmony of each choir must be complete even when all are singing together. Lasso disregards this rule, but its common-sense becomes evident when the choirs are on opposite sides of the building.

Archaic Instrumentation.—At the end of the 16th century monody arose. It was the art of non-polyphonic vocal declamation with an instrumental accompaniment. With characteristic acumen the Italian monodists promptly recognised that voices and instruments will not meet on the same plane of tone. Not all composers understood the new problems. The habit, in private performance, of using viols to replace missing voices in madrigals had gone far to make composers incautious in dealing with more penetrating instruments. The flat-backed viols with their husky and reedy tone (nowadays still noticeable in the double-bass) were already giving place to the royal family of the violin in all its sizes; this family was no longer on singing terms with voices; yet many composers at first saw no difficulty in using any instrument as equivalent to any other instrument or voice at the same pitch. Schütz (1585–1672) writes for triple and quadruple choirs of voices mixed with instruments. He writes the words under the instruments as well as under the voices; he often merely designates a part *Vox instrumentalis*; but he also takes the trouble to suggest *Tromba o flauto*, as if these instruments, in low register, had the same weight! Beauty often emerges from the chaos—associated with some practical suggestion that leaves us in doubt whether the composer knew what he achieved; as when Schütz proposes that his wonderful *Lamentatio Davidi*, a perfectly scored masterpiece for bass voice, 4 trombones and organ, should be played with two violins an 8vo higher as a substitute for the first two trombones!

Continuo Instrumentation.—By the time of Bach and Handel instrumentation had become a mature art; but an art depending on conditions no longer familiar to us. When these conditions are restored the resulting aesthetic system completely justifies itself. It recognises that no group of instruments can make homogeneous harmony like a vocal chorus, but that all instrumental scoring consists normally of a top, a bottom, and a *tertium quid* that completes the harmony but remains in the background. Bass instruments support the bass; all other instruments, whatever their pitch, are aesthetically top parts, and their most elaborate counterpoint does not profess to make their tones blend. They are woven into patterns of coloured threads, not blended like the colours of a landscape. The *tertium quid* is provided by an organ or a harpsichord; and it obeys the normal grammar of choral harmony. Only a keyboard instrument can provide such harmony ready-made on one plane of tone. At the present day one of the commonest faults of unimaginative scoring is the habit of treating the orchestra like a 4-part chorus. Continuo orchestration shows the true principle with drastic clearness, but it

shelves the problem of how to keep subordinate parts in their places. The continuo player represents an army of slaves upholding an aristocratic civilisation.

Besides gaining a capacity to attack discords boldly, the vocal chorus has undergone a radical change in the treatment of the bass voice when supported by instruments. When the tenor is low but still inferior to the harmony, the bass is no longer obliged to go lower, but is free to sing in its upper register, crossing freely above the tenor but relying on instruments which double it an 8vo lower as the true bass. Bach and Handel never once cross the bass over the tenor in any other way; the tenor in such places never gives the true bass. And Bach's so-called unaccompanied motets thus show in every line that they were conceived as supported by at least an instrumental bass. In fact, unaccompanied choral writing practically disappears from classical music between Palestrina and Schubert. It appears modestly in part-songs, and is first taken fully seriously by Brahms; though some older conductors of choral societies honourably kept up its tradition.

The basis of the continuo orchestra was, as now, the string band, an instrumental chorus of first and second violins, violas and violoncellos, supported an 8vo lower by double-basses which are never independent. Wind instruments did not form a complete mass of harmony but stood out against the strings in double or triple threads of each timbre, except when (as often in Handel) they doubled the strings. Flutes were used much more in their lower registers than we think fit in modern orchestration. In the organ-loft of a vaulted building low flutes are more effective than in ordinary concert-rooms. The ordinary flute is called *traverso*. The term *flauto*, with the use of the treble clef on the bottom line, indicates the *flute-à-bec*, a kind of flageolet, with rather a higher range. Bach uses pairs of each kind in the *Matthew Passion* but not in the same movements.

Oboes are also used in threes or pairs, and the ordinary oboe alternates with a variety a 3rd lower, the oboe d'amore, with the bell (and therefore the tone) of a cor anglais. Strauss has revived it. The real cor anglais figures in Bach's orchestra as the oboe da caccia or the taillie. Some authorities tell us that one or other of these was not an alto oboe but a tenor bassoon. It is easier to relabel a museum specimen than to rewrite the whole of Bach's oboe da caccia music.

Bassoons hardly ever emerge from doubling the bass. The *Quoniam* of Bach's B minor Mass is a bass solo accompanied by a horn, two bassoons and continuo. It would be delicious if we could find proper acoustic conditions for it and could handle the continuo discreetly enough. A great moment is the rising of the spirit of Samuel in Handel's *Saul*, where the bassoons are as ghostly and awesome as the prophet's message. In large enough numbers they would also astonish us in Handel's scoring of the "thick darkness" in *Israel in Egypt*. Handel, whose oratorio performances were on a large scale, must have had more reed-tone than string-tone in his orchestra; for he often had 20 oboes and 20 bassoons. Multiplication greatly mellows the tone of an instrument; and we, who seldom hear more than 4 oboes in unison, even in Mahler's 8th symphony, must not hastily judge our ancestors on this point.

Trumpets and horns, not being provided with modern valves, could produce only the natural harmonic series of the key to which their length of tube was set. That series does not close up into anything like a scale until the 8th harmonic. Accordingly trumpeters devoted themselves to acquiring extraordinary command of the delicate distinctions of high lip-pressures (*embouchures*) between the 8th and 20th harmonics. A long mouthpiece, with a little play in its adjustment, enabled the trumpeter to correct the out-of-tune 11th, 13th and 14th harmonics. (This secret was already forgotten by 1785, so that Burney, describing the Handel Centenary Festival, tells us that whenever the G and G \sharp , alternately represented by the 11th harmonic, were heard in "The trumpet shall sound" displeasure was seen on every countenance.) Humbler players called themselves *Principal-bläser* and produced the lower notes to which the tight-lipped clarino-player could not descend. Horn-players developed a similar hazardous technique of high notes. In modern performances special training and special instruments are required for early 18th century trumpet and horn

music. A modern tendency to strain all instruments up to high notes has facilitated this revival. Trombones, when they occasionally appear in continuo orchestration, are treated exactly like choral voices, and are, indeed, mainly used in unison with the chorus. A soprano trombone at first completed the group but Bach already had to replace it by some kind of slide-trumpet (*corno da tirarsi*).

Bach's full orchestra consists, then, of the string band (preferably larger than he ever had) oboes (ordinary or *d'amore*) in pairs or threes, flutes or flutes-à-bec in pairs or threes, bassoons (taken for granted) in unison with the basses, three trumpets (two clarini and one principal) three horns (not often used together with the trumpets) and a pair of kettle-drums. If the string band is large the wind parts, other than the trumpets, should be doubled, trebled, or (in festival performances) multiplied. The organ supplies the continuo in choruses, and the harpsichord supplies it in solo movements. The pianoforte is really (as Philipp Emanuel Bach already urged) better than the harpsichord, if only the player will avoid a self-assertive touch.

The orchestral combinations of solo movements range from Handel's perfunctory *tutti unisoni* to Bach's and Handel's richest schemes. Instruments obsolescent from incompatibility or feebleness live awhile in the arias and recitatives, protected from competition with the orchestra; and so we learn from Bach's *Passions* and *Trauer Ode* the use of the lute and viola da gamba, and from Handel's *Alexander Balus* the use of the theorbo, a large double-necked lute. Each movement has its own scheme of instrumentation as a set pattern which cannot change while the movement lasts.

The scheme of a chorus with independent full orchestra is in three planes of tone. These planes do not interfere with each other, and each plane has variants of the same harmonic scheme which would produce appalling collisions if all were projected on to a single plane (say, in an arrangement for two pianofortes). The principal plane is that of the voices. Above it, mostly higher in pitch, all the instruments that are not doubling the bass flourish with more rapid detail than the voices. Behind, and supporting the whole, is the continuo which moves more slowly than the chorus. The bass is common to all the planes, though it is enlivened by instrumental details. The results of this scheme, realised by competent execution under scholarly guidance, are as true in our age as they were when Bach and Handel wrote. Scholarship must show us the right conditions for performance, but it need not recover too precisely the actual original conditions. An old man who had been a chorister under Bach at Leipzig once told Wagner's teacher, Weinlig, how Bach's cantatas were performed. His account was, "It went atrociously and we always got a flogging afterwards."

Symphonic Orchestration.—Gluck (*q.v.*) laid down one of the cardinal principles of symphonic as well as dramatic orchestration when he said that instruments ought to be used according to dramatic vicissitudes. This means that for Gluck it is neither sufficient nor often possible to use them according to a set pattern. Another cardinal principle results from the disappearance of the continuo. This first happened merely by neglect, as the severe training needed for it repelled a generation of musicians excited by non-polyphonic styles. But mere neglect soon passed into a disposition to make the orchestra provide its own continuo. If old music sounded hollow without a continuo, why should not new music contrive better? This at once put many instruments into categories unrealized by Bach and only sporadically realized by the eclectic Handel. An instrument could now have two values: one, the old cantabile function; the other a capacity to provide unobtrusive notes for the background. Holding-notes for the horns revealed a wonderful beauty and usefulness in this way, with all a singer's power to swell and diminish the sound.

The bassoons became the hardest worked wind instruments in the early symphonic orchestra, for they could do everything required of continuo-work, from doubling the bass to supplying the many notes the natural horns could not reach. Their tone, so beautifully if unwittingly described in *The Hunting of the Snark* as "meagre and hollow but crisp, like a coat that is rather too

tight in the waist, with a flavour of will-o'-the-wisp" had a most useful capacity for vanishing; and "too tight in the waist" is a very apt description of instruments which, like the bassoon and the viola, show in their half-veiled tones the results of a compromise between the dimensions proper to their pitch and the practicable stretch of human hands.

The viola had at first a curious position in the early symphonic style. That style was so unpolyphonic that the viola could for a long time find nothing to do but to double the violoncello in the upper octaves as the basses double them in the lower. The result is so good that in early symphonies it is carried out mechanically even where it takes the violas above the second violins. But Mozart uses this primitive device with full imaginative insight in mature works where he hardly less often divides the violas into two independent parts.

The trumpets of the symphonic orchestra have become degraded to the fanfares and signalings of the *Principal-bläser*. The clarino player was finally ousted by players of a cheap substitute called the clarinet, which could play high trumpet parts with ease, if with rather a vinegar tone. But the clarinet had a wide compass; these trumpet-sounds are its worst. Below them it had a rich cantabile octave, and below that a few rather dull notes; and below these a coldly mysterious and reedy lowest octave, the chalumeau register. The dull middle notes proved astonishingly useful for continuo purposes; they are higher than the bassoon can attain without self-assertion, and they are not limited like the horn notes. Gluck uses the clarinet only in this neutral region; and even Mozart gives the instrument nothing better when the orchestra is in the key of D. This primitive treatment survives as late as Beethoven's 2nd Symphony, and revived by him in quite a late work, the fugal overture, *Zur Weihe des Hauses* (op. 124).

But when Mozart uses clarinets in the keys of A major, E major, E flat and B flat he reveals the clarinet as richer and more resourceful than any other wind instrument. The chalumeau octave is deliciously nutty in arpeggios, and dramatically hollow in sustained notes. The cantabile octave is magnificent (see the trio of the minuet of the great E flat symphony, for its contrast with echoes on the flute and with low arpeggios on the second clarinet). The military high notes (or "fife sounds") Mozart does not care for. Beethoven's view of the clarinet is less sympathetic than Mozart's, his idea of its cantabile register being just a tone too high. Schubert understands it perfectly.

The oboe can never efface itself. Run through the individual wind-parts of some such encyclopaedic score as Wagner's *Meistersinger* and you will be astonished at the unfailing beauty of the oboe parts and at the large tracts of drudgery in the excellent, uncomplaining clarinets.

The flute has no power in its lower octave and blends with other instruments in none, except, paradoxically, with extremely high Bach-like trumpet notes (if the experiment were ever tried). But in its top octave (from A to A) it is a very adequate and euphonious treble to the wind-band, and gains greatly by doubling. Haydn hardly ever writes his orchestral flutes high enough and often seems to expect low notes to be heard under conditions that would not have satisfied Bach. It is possible that his long period of experiment at Esterhazy did him less good than he or historians have thought. His Esterhazy symphonies show that he had a primitive orchestra diversified by astonishing solo players. He was able at Esterhazy to produce horn-passages that would astonish Bach. But in the world outside he found that orchestras, though better in the rank and file, were seldom troubled by virtuoso members. In his last symphony the theme of the finale is a typical and easy horn tune, but he dare not give it to the first horn of Salomon's London orchestra except under cover of a tutti! All his mature scoring is full of strokes of genius but deeply marked with signs of disillusion.

Beethoven's Instrumentation.—Beethoven enlarged the range of orchestral thought more than any composer between Gluck and Wagner. The circumstance of his deafness made him the victim of some miscalculations; and pedantic views of orchestration lead many critics to exaggerate these into grounds for a worse perkiness than Rimsky-Korsakov's damaging patronage of

Beethoven's scoring. Two things must be learnt by everybody who wishes to understand Beethoven; first, that errors of calculation are not the same thing as errors of imagination; secondly, that a symphony is not an opera. Beethoven's errors of calculation are no greater than those of any composer who has not been able to hear a rehearsal of his own orchestral work. Their correction, as shown by Weingartner (*Ratschläge*), is equivalent to any piano-forte player's control of his own touch, and would amount to little more than a conductor's ordinary exercise of his skill were they twice as extensive.

Errors of imagination do not exist in Beethoven's art; and only a school of criticism by rule of thumb would suppose that they did. Compared with Mozart's, Beethoven's scoring is rough, redundant and capricious. But Beethoven's ideas are not Mozart's and can be expressed neither in Mozart's nor in Wagner's scoring. When critics tell us that bars 5-8 of the first movement of Beethoven's 8th Symphony are badly scored, all they mean is that to let two oboes and a flute crowd in upon a quiet phrase in the clarinet is not a proper way to score the first fateful appearance of a Wagnerian *leit-motif*, which may not be heard again for an hour. But it is an admirably dramatic and symphonic way to score a formal phrase which is going to be shouted at the top of the full orchestra immediately afterwards. The conductor need only say four words to the oboes, "Let the clarinet through," and the passage becomes perfectly clear. But it is already intelligible without any such precaution, and only bad playing can spoil it.

The symphonic orchestra which suffices for Beethoven, and for Brahms two generations later, consists of strings, pairs of flutes, oboes, clarinets, and bassoons, one or two pairs of horns, a pair of trumpets and kettledrums. Trombones, reserved for climaxes, are used in spacious 3-part harmony, and Beethoven requires them in three sizes, alto, tenor and bass. For lack of the alto trombone many of Beethoven's top notes must nowadays be lowered; and then our smart young orchestrators blame Beethoven for his ill-balanced chords. The full wind tone is extended upwards by the dangerously shrill piccolo, and downwards by the contrafagotto which gives the bass a richness without asserting itself. The big drum, cymbals and triangle are called "Turkish music" and, when used at all by Beethoven, are used according to Viennese ideas of Turkishness. Beethoven's intentions, whatever we may think of their execution, cover the whole field of symphonic art; and it is to dramatic orchestration that we must look for any addition to his range of thought.

Dramatic Orchestration.—The change from continuo-orchestration to the symphonic style was, as we have seen, essentially a change towards drama. Hence the dramatic and symphonic styles do not become separated at once; and with Mozart, who was equally happy in both, they are not easy to distinguish. The distinction is, even in Mozart, a paradox to people who think that opera is the most dramatic form of music. Sonatas and symphonies, even by Mozart, turn out to be far too dramatic for the stage. The fight at the beginning of *Don Giovanni* is perfectly adequately represented in musical sequences which would be too cold for any but his earliest symphonies. Theatre music will no more stand a symphonic environment than stage scenery will stand daylight.

And yet there is no limit to the refinement of dramatic orchestration whether in Mozart or Wagner. The gradations that a symphonic composer uses in 20 bars must be spread over a hundred in any continuous part of an opera, even on Mozart's scale. Here we already have a reason why opera should encourage very delicate gradations. Wagner's scale is given by the three minutes of the chord of E flat at the beginning of *Das Rheingold*; but still more significant is his management of a tensely emotional quarter of an hour with no more orchestra than strings and two horns, without double-basses, in the first act of *Die Walküre*. His enlargements of the orchestra all have an ultimate effect of purifying the timbre and so removing complications from the method of scoring. There was nothing new in large orchestras: both Mozart and Beethoven had rejoiced in performances with double wind; and in Wagner's early Dresden days Spontini requisitioned "douze belles contrebasses" for the performance of his operas. The experienced

Wagner of Bayreuth is contented with eight.

A great stimulus was given to all orchestration by the invention of ventral trumpets and ventral horns. When these instruments thereby acquired a complete scale the aesthetics of all brass instruments needed reconsideration. Unimaginative composers of course saw no difficulty. A trumpet penetrates everything else like a red-hot poker, so why not give it the melody in every tutti? Wagner thought otherwise; he felt that brass tone was coarse unless it was used in large harmonic masses, and he accordingly invented new brass instruments to make the masses complete and coherent. Meanwhile he took his wind instruments in threes instead of twos. Already in the comparatively simple scores of *Der Fliegende Holländer* and *Lohengrin* this greatly clarified the colour-scheme. Half the art of scoring for wind instruments in the classical symphonies consists in making the best of the fact that instruments of contrasted tones will not make homogeneous triads when taken in couples. In *Tristan und Isolde* the threefold arrangement (two oboes and cor anglais; two clarinets and bass clarinet) adds its advantages to the maturest Wagnerian harmony, with a polyphony as profound as that of Beethoven's last quartets. In the tetralogy of *Der Ring des Nibelungen* Wagner takes his wind groups in fours, and introduces his new brass instruments. They originated in the bass-tuba which had come to replace the grotesque ophicleide and the still more primitive serpent as a bass to the trombones. These makeshifts had served Mendelssohn's purpose and failed to serve Berlioz's. The tuba could put an imposing bass below the trombones. Its tone is fat and puffy whereas that of the trombone is red-hot. A sensitive ear may notice, and a wise ear may refuse to notice, that the tuba is putting a black line below the red. But Wagner saw the possibility of a new aesthetic value here; and so in his tetralogy five tubas ranging from contrabass to high tenor show as clear a contrast from trombones as oboes from clarinets (Rimsky-Korsakov utterly fails to grasp this point).

The composers, having learnt new powers from such enlargements, can henceforth use these powers without extra apparatus. The orchestration of *Die Meistersinger* is the most complex in all Wagner, just because it is written for Beethoven's orchestra plus one tuba and a harp, and, of course, the now ubiquitous ventral horns, the most perfect of all continuo-players. In *Parsifal* the extra tubas are abandoned but the remaining contrabass-tuba has permanently won its independence of the trombones.

It seems paradoxical to leave Berlioz out of account in a history of instrumentation. Yet, short of a detailed appreciation of his individual strokes of genius, all that can be said of him is that he drew attention to the subject in an epoch-making but capricious treatise, and that he achieved all that was possible to a highly imaginative musician who happened to hate polyphony. And that is more than some critics might expect. But it cannot have much direct influence on more ordinary musicians.

Post-Wagnerian Instrumentation.—A great many loudly proclaimed "new" tendencies in orchestration are nothing but the discovery of some single elementary principle. It would be quite easy to write a history of post-Wagnerian scoring in which single characteristics from each of the historic schools here described were assigned haphazard, one to each living composer; and quite impossible to argue against its results. The silliest *a priori* theories seem incontrovertible if we forget how music is actually made. If, for example, we believe that music is made for instruments instead of instruments being built to make the best music they can, we may come to believe in the theory ascribed to Stravinsky, that each instrument should produce no passages that are not peculiar to its own timbre and inappropriate to any other. This is as if no gentleman should ever say anything that could be said by a lady; and vice versa.

When we have dismissed all such precious nonsense, several real phenomena remain. New harmonic ideas, such as multiplanar harmony, depend inextricably on instrumentation as surely as did the classical grammar of counterpoint. Less important is what Richard Strauss has called *al fresco* orchestration. This means a perception that there is not only safety in numbers, but a high aesthetic value in the average result of sixteen wild-cat attacks at

a passage that no individual can play properly. It is doubtful whether that is the real reason of the splendour of such passages. For one thing, the splendour is enhanced by rehearsal, and in the best orchestras the players eventually learn such passages fairly accurately.

Mahler made a systematic study of the possibilities of very large orchestras; almost a quarter of the size of that of our Crystal Palace Handel festivals, but with music specially written for them. His 8th Symphony is a choral symphony requiring at least 750 performers, and going much more satisfactorily with 1,000. Berlioz never really contemplated anything larger. Such propositions are not decadent; they are severely disciplinary and require an imagination of the highest efficiency. On a large scale most orchestral colours fade; especially horns, which must be greatly multiplied if they are to tell.

More fascinating to most artists, and more practical in the present lean years, are the aesthetics of small groups and chamber-orchestras. But this is a subject which cannot be pursued here. It is as much as a young composer's prospects are worth to come before modern critics without a new aesthetic system of his own invention. But a general article cannot deal with such private affairs.

(D. F. T.)

INSTRUMENT OF GOVERNMENT, the name given to the decree, or written constitution, under which Oliver Cromwell as "lord protector of the commonwealth" governed England, Scotland, and Ireland from Dec. 1653 to May 1657.

The Long Parliament was expelled in April 1653 and the council of state dissolved; the Little, or Nominated, parliament which followed ended its existence by abdication; and Cromwell, officially lord general of the army, with a new council of state, remained the only recognized authority in the country. It was in these circumstances that the Instrument of Government, drawn up by some officers in the army, prominent among whom was John Lambert, was brought forward, and after certain emendations accepted by Cromwell on Dec. 16. Consisting of 42 articles, the Instrument placed the legislative power in the hands of "one person, and the people assembled in parliament"; the executive power was left to the lord protector, whose office was to be elective and not hereditary, and a council of state numbering from 13 to 21 members. The councillors were appointed for life; 15 were named in the Instrument itself, and Cromwell and the council were empowered to add six. To fill vacancies parliament must name six persons, of whom the council would select two, the choice between these two being left to the protector. A parliament was to meet on Sept. 3, 1654, and until that date the protector with the consent of the council could make ordinances which would have the force of laws. After the meeting of parliament, however, he had no power of legislation, nor had he any veto upon its acts, the utmost he could do being to delay new legislation for 20 days. A new parliament must be called "once in every third year," elaborate arrangements being made to prevent any failure in this respect, and for five months it could not be dissolved save with its own consent. The parliament, composed of a single chamber, was to consist of 460 members—400 for England and Wales, and 30 each for Scotland and Ireland—and the representative system was entirely remodelled, growing towns sending members for the first time, and many small boroughs being disfranchised. A large majority of the English members, 265 out of 400, were to be elected by the counties, where voters must possess land or personal property of the value of £200, while in the boroughs the franchise remained unaltered. In Scotland and Ireland the arrangement of the representation was left to the protector and the council. Roman Catholics and all concerned in the Irish rebellion were permanently disfranchised and declared incapable of sitting in parliament, and those who had taken part in the war against the parliament were condemned to a similar disability during the first four parliaments. The protector was empowered to raise a revenue of £200,000 in addition to a sum sufficient to maintain the navy and an army of 30,000 men, and religious liberty was granted "provided this liberty be not extended to Popery or Prelacy." The chief officers of state were to be chosen with the consent of parliament, and a parlia-

ment must be summoned at once in case of war. The practical effect of the Instrument was to entrust the government of the three countries to the parliament for five months out of every three years, and to the protector and the council for the remainder of the time. Although the Instrument bristled with possibilities of difference between parliament and protector, "it is impossible," as Gardiner says, "not to be struck with the ability of its framers."

Cromwell governed according to the Instrument until the meeting of parliament on Sept. 3, when he endeavoured to obtain parliamentary sanction for the Instrument. Prolonged disputes followed and he dissolved the parliament on Jan. 22, 1655, without obtaining his object. Regarding the Instrument as still in force, the protector sought for a time to rule in accordance with its provisions; but new difficulties and growing discontent forced him to govern in a more arbitrary fashion. A second parliament met in Sept. 1656, and in the following May Cromwell assented to the Humble Petition and Advice, which supplanted the Instrument of Government.

The text of the Instrument is printed in S. R. Gardiner's *Constitutional Documents of the Puritan Revolution*. See also S. R. Gardiner, *History of the Commonwealth and Protectorate*, vols. ii. and iii. (1897-1901); L. von Ranke, *Englische Geschichte* (1859-68); and T. Carlyle, *Cromwell's Letters and Speeches* (1897-1901).

INSTRUMENTS, ELECTRICAL. On account of the great extension of electrical power supply, cable and radio telegraphy and telephony, and research, electrical measuring instruments have become extremely numerous of recent years; and it is therefore desirable to preface a description of the leading types by a short summary and classification of their principles.

In order that an electric current should flow through a conductor, there must be a potential difference, or P.D., usually expressed in volts, between its ends. The resulting current expressed in amperes always produces two effects: (a) an external magnetic field encircling the conductor and proportional to the current, and (b) an internal heating of the conductor due to agitation of its molecules which is proportional to the square of the current. If the conductor is a liquid compound or electrolyte, the passage of the current also produces a separation of its constituents or electrolysis, causing a liberation of gas or deposition of metal, the amount of which is proportional to the current and to the time for which it passes. All these three effects of the current have been employed as bases for its measurement. Conversely, the introduction of a magnetic field into a circuit (dynamo or transformer), or the heating of the junction of two conductors (thermopile), or chemical action (voltaic cell) causes an electromotive force to be set up, and electrical instruments based on these effects are in use. In addition when a difference of potential exists between two conductors there is an electrostatic attraction between them which can be used as a method of measuring the P.D.; and when electrified particles or electrons are projected across a vacuum space as in a valve tube they can be deflected either by electrostatic attraction or a magnetic field.

The steady current in a metallic conductor in amperes is equal to the P.D. in volts between its terminals divided by its resistance in ohms; and resistance measuring devices form a very important section of electrical instruments, with which are associated potentiometers for P.D. and current measurement. The power taken from or imparted to a circuit in Watts at any instant is obtained by multiplying the P.D. in volts by the current in amperes at that instant, and wattmeters enable this power to be directly indicated; while the energy consumed, generally measured in kilowatt hours or Board of Trade units (B.T.U.), is obtained by multiplying the power in kilowatts (1,000 watts) by the time in hours it is utilized, and is registered by energy meters; but if the supply P.D. is constant the product of the current and time or quantity of electricity is sufficient and is indicated by *quantity meters*.

Inductance and capacity are two electrical quantities which are of great importance in electrical circuits especially with high frequency alternating currents. The former is the magnetic field which is linked with the circuit whenever a current flows through

it, and therefore produces an e.m.f. whenever the current is increasing or diminishing, just as a mass resists acceleration or change of its velocity. The unit of inductance is termed the Henry (after the American physicist Joseph Henry, *q.v.*) and is such that it requires 1 volt to increase the current in it at the rate of 1 ampere per second. Capacity on the other hand has the opposite effect to inductance, as it offers infinite resistance to a steady motion or current, but allows alternating current to pass. It is the analogue of a spring which yields to changes of force, but remains stationary for a steady force.

Electrical and magnetic measurements are so closely related that they must be considered together, and we have to deal with magnetic force corresponding to electrostatic force, and magnetic flux corresponding to electric current.

The classification of electrical measuring instruments may be set out in the following table:—

Quantity to be measured	Practical unit	Definition of unit	Measuring instruments	
			Indicating	Laboratory
Current	Ampere	0.00111800 grams of silver deposited per second	Ammeters	Galvanometers and voltmeters
Resistance	Ohm	106.300 centimetres of mercury 1 sq. mm. section (14.4521 grams) at 0° C	Ohmmeters	Wheatstone bridges
Electromotive force (e.m.f.) or Potential difference (p.d.)	Volt	Applied to resistance of 1 ohm produces a current of 1 ampere	Voltmeters	Resistance standards
Power	Watt	1 Volt-ampere	Wattmeters	Electrometers or potentiometers and standard cells
Quantity	Coulomb	1 Ampere-second	Quantity meters	Voltameters or ballistic galvanometers
Energy	B.T.U.	1 Kilowatt-hour	Energy meters	Inductance and capacity bridges
Inductance	Henry	1 Volt for increase of current at 1 ampere per second		Standard inductances
Capacity	Farad	1 Coulomb for 1 volt		Variometers
Magnetic force	Gauss		Permeameters	Standard condensers
Magnetic flux	Maxwell		Fluxmeters	Magnetometers
				Ballistic galvanometers

I. STANDARD INSTRUMENTS

The two primary electrical units are those of current (ampere), and resistance (ohm). From these can be derived the unit of potential difference (volt) and any one of these three can be deduced by Ohm's law from the remaining two. Standard instruments are divided into two classes (*a*) primary, and (*b*) derived or practical; the first, demanding extreme care and accuracy in design and construction, are being confined to the standardizing laboratory, the second being convenient portable devices for reproducing the standard.

The two primary standard instruments employed at Government standardizing institutions such as the National Physical Laboratory are the *current balance* for determining the ampere, and the *Lorenz apparatus* for determining the ohm. The former (fig. 1) is a highly accurate form of Kelvin current balance (*q.v.*) in which both the fixed and moving coils are wound in screw threads cut on marble cylinders of accurately measured dimensions, and the force on the moving coils due to current circulating through the whole system is measured by an accurate balance. This instrument is generally connected to a silver voltameter, consisting of a platinum bowl containing a solution of pure silver nitrate and a plate of pure silver held horizontally in the liquid. On passing current from the silver anode plate to the platinum bowl, silver is deposited on the latter, and the amount of the deposit can be found by weighing the bowl before and after the deposition. Such a silver voltameter constitutes the derived practical standard of current, and can be set up in any laboratory. The "International ampere" was defined by the International Conference on Electrical Units and Standards in 1908 as "the unvarying electric current, which, when passed through a solution of nitrate of silver in water, in accordance with specification II. attached to these resolutions, deposits silver at the rate of 0.00111800 of a gram per second." The more recent work of Dr. F. E. Smith at the National Physical Laboratory indicates

that the true ampere should deposit 0.00111828 gram per second.

The best primary standard instrument for the determination of the ohm is that originally due to Lorenz in 1873. Essentially it consists of a metal disc (fig. 3) rotated steadily in the magnetic field of a coaxial cylindrical coil through which a current is passed. The arrangement is therefore equivalent to a "Faraday disc" in which the magnet is replaced by the current carrying coil, and an e.m.f. is induced between the centre and edge of the disc. If M is the coefficient of mutual inductance between the coil and disc (the magnetic flux through the disc for unit current in the coil), i the current in the coil, and n the number of revolutions per second of the disc, any radius of the disc cuts across the whole flux Mi in each revolution or Mni lines of force or Maxwells per second. This is, by definition, the e.m.f., E between the centre and edge of the disc. The current passing through the coil is also led through the resistance R to be tested producing a P.D.

$V = Ri$, and the ends of this resistance are connected through a galvanometer G to two contacts at the centre and edge of the disc. On varying the speed of the disc a speed can be found for which the galvanometer remains at zero, indicating no current in which case $V = E$, or $Ri = Mni$, so that $R = Mn$. The mutual inductance M is a constant of the apparatus which can be calculated from the dimensions and number of turns of the coil and the diameter of the disc, so that when balance is obtained the resistance R can be determined by multiplying this constant by the speed, which is easily measured with accuracy.

The most recent form of Lorenz apparatus as designed and used at the National Physical Laboratory differs from the original form principally in having two discs and four coils wound on marble cylinders so arranged (*a*) that the system is astatic or unaffected by uniform external magnetic fields such as that of the earth, and (*b*) that the magnetic field of the coils at the edge of the disc is very low so that small errors in the dimensions have less effect. As the e.m.f.'s in the two discs are in opposite directions two contacts only on their edges suffice. The convenience of this apparatus enables standard resistance coils to be standardized directly, and this appears preferable and likely to be adopted in the future; but at present the practical derived standard is the mercury ohm consisting of a glass tube having a bore of 1 square millimetre in cross section and a length of 106.300 centimetres filled with mercury and at a temperature of 0° C. As the cross section of the tube is always determined by filling it with mercury and weighing the latter, the practical definition of the ohm has been modified, and the International ohm is now defined as "the resistance offered to an unvarying electric current by a column of mercury at the temperature of melting ice, 14.4521 grams mass of a constant cross-sectional area and of a length of 106.300 centimetres."

The mercury standard ohm is constructed by employing a glass tube having a perfectly uniform bore of 1 square millimetre cross

section (1.129 mm. diameter) which is carefully calibrated for uniformity of cross section along its length by measuring the length of a known small volume of mercury as it is displaced to different positions along the tube. The tube is then cut and carefully ground to the required length and two additional short lengths of it have bulbs blown on their ends and are cemented in exact line on to the ends of the main tube, with very thin sheets of platinum foil between. The foil is then perforated so as to make a continuous uniform tube with contacts at the exact length apart. This tube is filled with pure redistilled mercury and cur-

FIG. 1.—CURRENT BALANCE

rent is passed through it from bulb to bulb, while the P.D. between the platinum contacts can be balanced by a potentiometer and standard cell, thus giving the e.m.f. of the latter in terms of the ampere and ohm. Comparisons between the standard mercury ohm and a standard resistance coil can also be effected by a Kelvin double bridge. Whenever the mercury ohm is in use it is laid horizontally in a trough filled with melting ice. The testing current must be only a small fraction of an ampere to avoid heating the mercury, on account of its somewhat high temperature coefficient of resistance (0.090% per 1° C).

The mercury standard ohm is, however, far too difficult to construct to be of practical use, and consequently the standard resistances which are generally employed are in the form of platinum-silver or manganin coils carefully annealed and adjusted and standardized against the mercury standard at a standardizing laboratory. Many standard resistance coils have been devised, such as the original B.A. standard having a platinum-silver coil embedded in paraffin wax, the manganin standards of the Reichsanstalt and the more open forms of Fleming Burstall and Drysdale.

Having defined the ampere and ohm, the International volt is therefore defined as "that electrical pressure which, when steadily applied to a conductor whose resistance is one International ohm, will produce a current of one International ampere."

As in the other cases a practical standard is desirable, and this is provided by a standard cell, of which the best and now universally used example is the cadmium cell first devised by Dr. Weston in 1892. This cell as now made consists of a small glass vessel of H form (fig. 2) having platinum wires sealed into the bottoms of the main tubes. At the bottom of one of them a small quantity of mercury is placed, and in the other some 10% (by weight) cadmium amalgam.

Above the mercury there is a layer of mercurous sulphate and cadmium sulphate pastes, and above the amalgam, a layer of cadmium sulphate crystals. Some cadmium sulphate crystals are also placed over the above pastes, and the remaining space in the two main tubes and the connecting tube is partly filled with saturated acidic cadmium sulphate solution, the upper ends of the main tubes being hermetically sealed. In order to make the cell more portable by reducing the risk of displacing the contents, Dr. F. E. Smith introduced constrictions at the lower part of the tubes, these

BY PERMISSION OF CAMBRIDGE INSTRUMENT CO.

FIG. 2.—METHOD OF MOUNTING WESTON NORMAL CELL

constrictions preventing movements of the solid chemicals. The utmost care must be taken over the purity of the materials and cleanliness of the glass vessel and seals, and when the cell is made to the specification its e.m.f. is 1.0183 International volts at 20° C with a temperature coefficient of -0.004% per 1° C. The e.m.f. at any temperature t° C is given by the formula

$$E_t = E_{20} - 0.000,0406 (t - 20) - 0.000,000,95 (t - 20)^2 + 0.000,000,01 (t - 20)^3$$

The standard cadmium cell properly made up is the most accurate and convenient of all practical electrical standards, and measurements of any P.D. can be conveniently made with it, in conjunction with a potentiometer (*q.v.*). Another standard cell is the Clark cell. In this cell the cadmium of the Weston cell is replaced by zinc. The negative pole of a Clark cell consists of

an amalgam containing 10% of zinc; a positive pole, a pure mercury drop, covered with a mercurous sulphate paste; the electrolyte is a solution of zinc sulphate with excess crystals. In all other respects the construction of the Clark cell is similar to the Weston cell. The e.m.f. of the Clark cell at a temperature t° C is given by Watson as

$$E_t = 1.4326 - 119 \times 10^{-5} (t - 15) - 0.7 \times 10^{-5} (t - 15)^2.$$

II. CURRENT MEASURING INSTRUMENTS

These can be divided into two chief classes: (a) Galvanometers

or sensitive laboratory instruments for measuring very small currents, and (b) ammeters or indicating pointer instruments for large currents. The former are practically exclusively on the electromagnetic principle, while the latter are very diverse in form, and may be either electromagnetic or thermal.

Galvanometers.—These can again be divided into two types, known as the moving needle and moving coil forms respectively. The first are derived from the original discovery of Oersted in

1820 that if a conductor is stretched straight over a pivoted magnetic needle and parallel to it, the needle tends to turn at right angles to the conductor when current is flowing through the latter. If the current is reversed the needle turns in the opposite direction. The same reversal effect is produced by moving the conductor to the under side of the needle, so that if the conductor is wound into a flat coil encircling the needle, all parts of it tend to deflect the needle in the same direction and the effect is enhanced. This was put into practical form as the first galvanometer by Schweigger in 1820. Since the deflecting force or torque due to the coil is resisted by the controlling torque of the earth's magnetic field, it was obvious that the sensitiveness would be increased by reducing the latter or its effect, and Nobili in 1825 therefore introduced the "astatic" needle system in which two equal magnetic needles were mounted with opposite polarities on the same vertical stem, one being inside and the other outside the coil. The system was suspended by a silk thread and provided with a light pointer. It was left, however, for Lord Kelvin in 1858 to produce the highly sensitive reflecting type of galvanometer (fig. 4) which has persisted with minor modifications to this day. He employed an astatic system like Nobili's but with each of the needles inside a coil, the currents in two coils being in opposite directions, so that the deflectional torque was doubled while preserving the small control of the astatic system. The needle system was composed of a thin vertical aluminium wire across which two sets each of three or four short pieces of hardened watch spring were cemented; the two sets being magnetized in opposite directions by being placed between the poles of a powerful electromagnet. Midway between the magnet systems, a light concave mirror was cemented to the aluminium stem (sometimes with a thin mica disc behind it to assist in damping the instrument), and the whole system was suspended by a single fibre of cocoon silk cemented to the top of the stem, from the upper bar of a frame. Each of the coils was made in two halves in ebonite cases hinged to the side of this frame so that they could be closed together like a book with the needles in the small space between, and the instrument was therefore generally known as the four coil galvanometer. The mirror was usually exposed through a small space between the upper and lower coil systems. The whole instrument was enclosed in a brass case and glass case on an ebonite base provided with levels and levelling screws, which enabled the base to be accurately levelled and the needles to swing freely in the small space between the coils. On the top of the case was a vertical brass rod on which was mounted a curved permanent magnet on a sleeve which permitted of its being raised or lowered or turned, and a tangent screw on the rod allowed the final turning to be effected gradually and accurately. This magnet being nearer to the upper than the lower needle system exercised a resultant control on it which could be varied to any extent by raising or lowering the magnet, and the zero could be adjusted by the tangent screw. A good galvanometer of this type wound with coils having a resistance of 6,000 ohms, when adjusted to have a periodic time of 20 sec.

FIG. 4.—KELVIN ASTATIC MIRROR GALVANOMETER

gave a deflection of about 8,000 mm. per microamp. on a scale at 1 metre distance.

Improvements were made in the magnet system by Broca and Paschen and great improvement in sensitiveness and definiteness of zero was secured by employing the quartz fibres invented by Prof. C. V. Boys in 1890, but the most remarkable advance has been made quite recently by Prof. A. V. Hill and Mr. Downing at University college in conjunction with Dr. Daynes of the Cambridge Instrument company. Their galvanometer is similar to the Kelvin four coil instrument above described, but the magnet system has been made still smaller and of the recently discovered cobalt magnet steel (steel with 35% cobalt) which has a much greater intensity of magnetization and permanence than any previous form of permanent magnet steel, while the mirror has been reduced to the smallest and thinnest dimensions compatible with optical efficiency. The needle system weighs only 0.0045 grams and is suspended by a fine quartz fibre. The coils are also made much smaller so as to obtain the maximum magnetic field for a given resistance. The great obstacle to the general use of the moving magnet galvanometer has been its disturbance by stray variable magnetic fields such as those produced by electrical machines or tramways in the vicinity, as no system can be made sufficiently perfectly astatic as to prevent such disturbance, and attempts have been made to shield the galvanometer against such disturbances by enclosing it in heavy bells of soft iron, but with only partial success. Within the last few years however a new nickel-iron alloy (78 nickel to 22 iron) known as *Permalloy* or *Mumetal* has been introduced, which has a remarkably high permeability in weak magnetic fields, and it was suggested by Drysdale that this would enable an effective magnetic shield to be constructed with only a small thickness of this alloy. Acting on this suggestion Prof. Hill and Mr. Downing made a cylindrical mumetal case for their new type of galvanometer and found that the shielding was so perfect that the galvanometer was unaffected by the starting and stopping of a motor within a few yards of it. This important improvement has enabled the full sensitiveness of the galvanometer to be utilized without difficulty, and a 1 ohm galvanometer of this type with a periodic time of 10 sec. has given a deflection equivalent to 50,000 mm. per microamp. on a scale at 1 metre distance, or about 500 times the equivalent sensitivity of the Kelvin galvanometer. This achievement may lead to the renewed popularity of the moving needle galvanometer which has been discarded in favour of the moving coil form owing to the freedom of the latter from magnetic disturbance.

Standard Galvanometers.—The instruments so far described have been designed to obtain the highest possible sensitivity, but before the advent of accurate direct-reading ammeters, the tangent and sine galvanometer, devised by Pouillet in 1837, was in

FIG. 5.—HELMHOLTZ TANGENT GALVANOMETER

very general use for current measurement. In its simplest form this galvanometer consisted of a short pivoted magnetic needle provided with a long light cross pointer moving over a scale of degrees, and mounted at the centre of a large vertical coil through which the current could be passed. This galvanometer was set up and rotated until the magnetic needle was in the plane of the coil when no current was passing. On making the circuit a magnetic field was produced in the coil perpendicular to the earth's magnetic field and combining with it to produce a resultant field to which the needle deflected. The magnetic field at the centre of a coil of mean radius r and number of turns n when traversed by a current of i amperes is $H' = 0.2 \pi n i / r$, and if H is the horizontal component of the earth's magnetic field the resultant field will be inclined to it by an angle θ such that

$$\tan \theta = \frac{H'}{H} = 0.2 \pi n i / r H \text{ from which } i = \frac{r H}{0.2 \pi n} \cdot \tan \theta.$$

If the dimensions of the coil and the horizontal intensity of the earth's field are known, therefore, the tangent galvanometer serves as an ammeter. The value of H in London may be taken as 0.18 but it is liable to variation owing to the proximity of iron objects, so that for accurate work it should be determined in situ.

The accuracy of the tangent galvanometer depends on the uniformity of the magnetic field of the coil in the neighbourhood of the needle, and this is only the case over a very small area. For this reason the magnetic needle should be as short as possible, but this is in itself insufficient, and a great improvement was made by Helmholtz who used two equal and parallel coils, separated by a distance equal to the radius of either (fig. 5). With this arrangement and large coils very perfect uniformity of the field is secured and the tangent law is very accurately followed. By a slight addition to the tangent galvanometer it can be used for the measurement of current in another way which has certain advantages. The addition consists of mounting the coils and compass box on a rotatable vertical axis and providing them with a pointer which travels over a scale fixed on the base and divided in degrees. The galvanometer is first set up and turned till its needle is at zero (*i.e.*, in the plane parallel to the coils and to the earth's field, as before) but when the current is switched on and the needle deflects, the whole system is turned round the vertical axis to follow the needle, until the zero of the compass box catches up with it. In this case the field H' of the coils rotates with, and is always perpendicular to them, so that when the zero catches up with the needle the galvanometer has been turned through an angle α such that

$$\sin \alpha = \frac{H}{H'}, \text{ and } i = \frac{rH}{0.2\pi n} \sin \theta$$

for a single central coil. For this reason the galvanometer so used is termed a sine galvanometer, and the method has some advantages as the needle is always in the same position as regards the field of the coils when reading, and the angle of rotation can be more accurately read on the fixed scale used for the coils. Although good tangent galvanometers can usually be used in either manner, the tangent principle has been more generally employed.

Ballistic Galvanometers.—The foregoing galvanometers are used for the detection or measurement of very small steady currents, and are therefore preferably damped so as to attain their steady deflection as quickly as possible without oscillating about it. There is another class of galvanometers, however, which are employed for measuring the extremely sudden charging or discharging of a condenser or inductance, etc., and are termed ballistic galvanometers as being equivalent to the ballistic pendulum for measuring mechanical impulses. If I is the moment of inertia of the magnet system, K the controlling torque per unit angle, T the total torque and a the deflecting torque per unit current we have

$$I \frac{\partial^2 \theta}{\partial t^2} + K\theta = T = ai,$$

and if the system is at zero

$$I \frac{\partial^2 \theta}{\partial t^2} = ai \text{ so that } I \frac{\partial \theta}{\partial t} = I\omega_0 = a \int_0^t i dt = aQ$$

where ω_0 is the initial angular velocity of deflection and Q the quantity of electricity which has passed through the coil, provided that it has passed before the system moves appreciably from its zero position. The initial kinetic energy of the system is $\frac{1}{2}I\omega_0^2$ and the system will swing until this is converted into potential energy

against the control which $= \int T d\theta = K \int_0^\theta \theta d\theta = \frac{1}{2}K\theta^2$, so that

$$\theta = \omega_0 \sqrt{\frac{I}{K}} = \frac{a}{I} Q \sqrt{\frac{I}{K}} = \frac{a}{\sqrt{KI}} Q. \text{ The maximum deflection on}$$

first swing of the galvanometer therefore measures the quantity which has passed, provided that it has all been converted to potential energy against the control and not dissipated in air resistance or damping. For this reason ballistic galvanometers

are made as undamped as possible by having somewhat heavy cylindrical magnets to offer the smallest air resistance. In other respects they are similar to other galvanometers.

Moving Coil Galvanometers.—The moving coil galvanometer arose from the discovery by Ampere, in 1820, that a conductor carrying an electric current tended to move transversely across a magnetic field. (*See ELECTRICITY.*) The first application of this

BY PERMISSION OF ELLIOTT BROTHERS

FIG. 6.—MOVABLE COIL GALVANOMETER

principle to galvanometers was by Sturgeon in 1836, followed, in 1867, by the Siphon recorder of Lord Kelvin; but this was used for recording cable signals, and d'Arsonval in 1882 introduced the first reflecting moving coil galvanometer. It consisted of a light rectangular coil of fine wire suspended by the thinnest possible wires between terminals as shown in fig. 6 between the poles of a vertical horseshoe magnet. In order to intensify the magnetic field, a soft iron cylinder was mounted inside the coil without touching it. On passing a current round the coil through the suspensions the coil turned and its movements were indicated by a concave mirror on the coil reflecting a beam of light on to a scale. This type of galvanometer still persists, but Ayrton and Mather improved it in 1890 by making the coil very narrow and discarding the iron core. Various minor improvements have since been introduced, notably by Moll, who employs an electromagnet for his field.

A good standard Ayrton-Mather type of moving coil galvanometer has a sensitivity of 800 mm. per microampere at a metre for a resistance of 400 ohms and periodic time of 6 sec., and the Moll galvanometer gives 200 mm. per microampere for a resistance of 50 ohms and periodic time of 1.3 sec.

These sensitivities are far below those of the corresponding moving needle types, but the moving coil galvanometer has the great advantage of being undisturbed by outside magnetic fields, and of having constant sensitivity. On the other hand it has the disadvantage of being heavily overdamped on short circuit, and of being less suitable for very low P.D. measurements such as those on thermocouples, owing to the high resistance of its suspensions. Up till recently the advantages in most cases heavily outweighed the disadvantages and moving coil galvanometers have consequently been in universal use for all but exceptional cases, but the introduction of the nickel iron magnetic screening by Prof. Hill and Mr. Downing may restore the moving needle instrument to favor.

Duddell Thermo-galvanometer.—Neither of the above types of galvanometer is of any use for alternating currents, and the great need for a sensitive alternating current galvanometer

especially for radio measurements, led Duddell in 1904 to adopt the Boys radio-micrometer for this purpose. This instrument consists in principle of a moving coil galvanometer consisting of a single loop of thin copper wire hung up by a quartz fibre between the poles of a magnet. The lower ends of this loop are soldered to two small vertical bars of bismuth and antimony which are soldered together to a small copper disc at their lower ends to complete the loop and form a thermo-junction. When heat radiation falls on this junction a current flows through the loop and deflects it, and Prof. Boys has used this instrument to measure the heat received from stars. Duddell utilized this instrument by fixing a "heater" consisting of a small length of Wollaston wire just under the junction, and the passage of a current through this heater warms the junction and deflects the coil.

Shunts.—The very high sensitiveness of reflecting galvanometers renders it frequently desirable to be able to reduce it by definite fractions so as to be able to measure larger currents, and this is effected by shunting the galvanometer. If a resistance of one-ninth of that of the galvanometer is connected across the terminals, $\frac{9}{10}$ of the total current passes through the resistance and only $\frac{1}{10}$ through the galvanometer, and if the resistance is $\frac{1}{9}$ or $\frac{1}{99}$ that of the galvanometer, $\frac{1}{10}$ or $\frac{1}{100}$ respectively of the total current passes through it. Shunt boxes in which the requisite resistances can be converted by plugs are therefore often employed, but must be made for the particular galvanometers they are to be used with. In 1894, however, Profs. Ayrton and Mather devised a "universal" shunt box which could be used with galvanometers of a fairly wide range of resistances, and these universal shunts are now most commonly employed.

Vibration Galvanometers.—The great extension of bridge or null methods of testing inductance and capacity, etc., has created a demand for highly sensitive galvanometers for alternating currents, comparable with those used for direct-current measurements. None of the alternating current instruments so far described in any way meet this requirement, and such measurements have generally been made with telephones as detectors. This, however, confines the measurements to audible frequencies, and there are other objections to their use, so that vibration galvanometers have come into favour. Such galvanometers are in principle direct current galvanometers of high and variable natural frequency and capable of being "tuned" into resonance with the supply, in which case they produce a vibrating streak of light on the scale and are exceedingly sensitive.

The first practical form of vibration galvanometers was that of Rubens (about 1895), which consisted of a vertical stretched wire carrying a magnet and mirror system and two coils like that of a moving needle galvanometer (*q.v.*) but non-astatic. By altering the tension on the wire and its length by two bridges like those of a monochord, the natural frequency of this system could be brought into unison or resonance with the alternating current in the coils, whereupon the spot of light on the scale broadened out into a long streak. This type was somewhat difficult to "tune." Duddell followed in 1910 by a vibration galvanometer on the lines of his oscillograph (*q.v.*), but with two long strips, a tension pulley, and two bridges which could be moved by a right and left handed screw. This instrument was remarkably sensitive and covered a frequency range from about 25 to 2,000 per second, but was liable to respond to harmonics on the wave form. In 1911 Drysdale, with the help of Tinsley, devised a vibration galvanometer, primarily for use with his A.C. potentiometer (*q.v.*), in which the moving system was like that of Rubens, but mounted on a silk fibre. The control was exercised by a large horizontal permanent magnet, the strength of which could be varied by varying the distance between its pole pieces and by sliding an armature or "magnetic shunt" along it, so that tuning could be effected without touching the moving system. In 1920 he substituted an electromagnet controlled from outside by a battery and rheostat, and this form has since been independently conceived and constructed by the Cambridge Instrument company. Moving coil variable bifilar suspension vibration galvanometers of great sensitivity have been introduced by Campbell, Gall and others, while a most ingenious single fibre unbalanced instrument has recently

been devised by Prof. Moll. All such instruments are extremely sharp in their tuning, and therefore require the frequency of the supply to be kept constant to within about 0.1% for their satisfactory use.

Oscillographs and String Galvanometers.—The extensive employment of alternating currents of all frequencies from 25 to thousands or millions of cycles per second has caused a great demand for instruments which will give a record of the variation or wave-form of such currents, just as the steam or gas engine indicator records the variations of pressure in the cylinder, and these instruments are known as oscillographs. Prior to their introduction, such wave forms were somewhat laboriously determined by an instantaneous contact method originally devised by Joubert, and the Hospitalier "Ondograph" based on this principle enables the form of the wave to be automatically traced on paper by a pen. But such methods can only deal with currents which vary in the same manner over some seconds or minutes of time, while the true oscillographs will deal with transient currents which may last only a few hundredths of a second.

Oscillographs are, therefore, galvanometers capable of following rapid fluctuations in the current, and may be either of the moving needle or moving coil type. The inertia of their moving systems must be as low as possible, their natural frequency of oscillation very high, and their damping as nearly as possible critical. For these reasons, the moving system must be as small and light as possible. Blondel in 1891 devised the first oscillograph on the moving coil principle, and was closely followed by Duddell who in 1893 produced the form of oscillograph which has since been most largely used in this country. In order to diminish the inertia of the coil to a minimum it was reduced to a single loop of fine phosphor bronze strip, and as with even this small inertia a large control was found necessary to obtain the high natural vibration frequency aimed at (10,000 per sec.), the two upper ends of this loop were attached to the terminals and the lower portion passed over a small ivory pulley which was pulled downward by a spring, so that both sides of the loop were equally strained nearly up to their elastic limit. The loop with its pulley and terminals was mounted on a brass plate and could be mounted between the poles of a powerful electromagnet, taking the place of the permanent magnet of the d'Arsonval moving coil galvanometer (*q.v.*). In order to obtain the strongest possible magnetic field iron pieces were fixed on both sides of and between the strips, and for observing the deflections a very small thin rectangular mirror was cemented across the two strips at their centre. Damping was secured by closing the front by a glass plate and filling the space with oil. On passing current round the loop, one strip moved transversely forward and the other backward in the gaps, so that the mirror was tilted sideways and deflected a beam of light projected on to it by an arc lamp. By suitable optical arrangements the reflected beam was focussed on to a photographic plate or film which could be dropped or driven vertically downwards, and the variations of current in the loop were then recorded as a wave on the film.

In order to enable the wave form of a constantly alternating current to be seen or projected on a screen, Duddell also introduced a second mirror caused to oscillate in a direction perpendicular to that of the first mirror, by a cam driven by a synchronous motor from the alternating supply mains. The reflected beam from the oscillograph mirror was caused to fall on this second mirror and then on to the screen, causing the wave form of the current to be exhibited as a continuous picture, owing to the persistence of vision.

In nearly all alternating current investigations it is desirable to have simultaneous traces of the variation of the current and the P.D. and for this purpose Duddell employed two loops side by side in the same magnetic field with an iron plate between them to keep the field as strong as possible. One of these loops carried the current to be recorded or was connected across a low resistance so as to shunt a fraction of the current when it was too large for the strip; while the other was connected, in series with a large non-inductive resistance, across the circuit so that the current through it was proportional to the P.D. at each instant. Each of

the loops was provided with mirrors and a third "zero mirror" was arranged between them, so that when the light from the arc fell on them three beams were reflected, giving the P.D. and current waves and the zero axis respectively.

Portable oscillographs on this principle have recently been introduced by the Westinghouse company in America and the Cambridge Instrument company in England, the vibrators being made up as separate elements each with its own permanent magnet, and the illumination being produced by a metallic filament lamp which is temporarily overrun during exposure of the film. For high voltages the electrostatic vibrator of Ho and Kato is often substituted for one or more of the vibrators in the outfit.

An ingenious oscillograph on the hot wire principle was devised by J. T. Irwin in 1907, but has not come into general use. In France, M. Dubois has recently devised an oscillograph of the soft iron type in which a tongue of soft iron is caused to vibrate between the poles of a permanent magnet, and communicates its motions to the mirror through a strip and pulley.

String Galvanometers.—In 1901 Prof. Einthoven introduced a form of galvanometer which has proved of great value for a large variety of work. It is similar in principle to the moving coil oscillograph but is much more sensitive, although incapable of working at such high frequencies. Instead of the loop a single straight fibre usually of silvered or gilded quartz is employed. This fibre is mounted in the narrow gap between the poles of an electromagnet as in the oscillograph, and moves transversely across this gap. As there is no second fibre to which to attach a mirror, the poles of the magnet are bored through so that a small portion of the centre of the fibre can be seen, and a compound microscope with a scale in its eyepiece is mounted in one of these holes and a condenser in the other. The movements of the fibre can therefore be observed and measured through the microscope, or the fibre and scale can be projected on to a screen by an arc lantern directed on to the condenser.

The Einthoven galvanometer is, unfortunately, very costly, owing to the difficult construction of its poles and optical observing arrangements, and an ingenious attempt at securing its advantages with the ordinary simple reflecting mirror device has recently been made by Mijneer van Dyck of Leyden in his "Torsion String" galvanometer. In this galvanometer the fibre is of the finest silicon bronze wire, and a second thin wire of hard drawn copper lies close to and parallel to it over the portion between the magnet poles and is soldered to it at its top and bottom. As the copper wire is of much lower resistance than the central bronze wire, the bulk of the current flowing down the latter is shunted into the copper wire which, therefore, becomes a moving coil with half a turn, and tends to rotate round the central wire, being controlled by the torsion of the latter. As the system is unsymmetrical and therefore unbalanced, a strip of aluminium foil is cemented across the two wires at their centre and a small silvered mirror is cemented on this strip on the opposite side so as to balance the loop, a cleft being made in the corresponding magnet pole to allow of its free rotation. This galvanometer can be used with the ordinary lamp and scale, and with a resistance of 10 ohms and periodic time of 0.01 sec. is stated to give a deflection of 3 mm. per microampere at 1 metre, which is nearly equivalent to the sensitivity of the Einthoven galvanometer.

Cathode-ray Oscillographs.—For frequencies higher than about 2,000 ~ per second, all the above types of oscillograph are unsuitable, and for higher frequencies up to those employed in radio work the cathode-ray oscillograph has come into use. If a high P.D. is applied between two plates in a very perfectly evacuated tube, negatively electrified particles or electrons are ejected from the negative plate and travel in straight lines with high velocity across the tube. Such a stream is known as a beam of cathode rays, and when it falls on a phosphorescent screen a brilliant illumination is produced. (See *ELECTRICITY: Conduction of in Gases.*) A filament may be substituted for the negative plate and gives out electrons when heated by passing a current through it, especially when it is coated with lime or thorium oxide as in "dull emitter" valves. If such a heated filament is enclosed in an evacuated bulb near to two plates each perforated by a fine hole,

and a high P.D. is applied between the filament and a ring near the plates, the electrons are driven towards the plates with high velocity, and some of them pass through the holes forming a very narrow pencil of cathode rays. When such a pencil passes between two plates and a P.D. is applied between them the electrons are attracted towards the positive plate and the beam is deflected in that direction; while if the plates are the poles of a magnet the electrons tend to move transversely between them like a conductor carrying a current and a deflection in the perpendicular direction is produced. The most simple oscillograph on this principle is known as the "Braun tube," having been invented by Braun in 1897, and a tube of this kind is now manufactured by the Western Electric company. It is composed of a conical highly evacuated glass bulb having the larger end coated inside with a layer of zinc sulphide or other luminescent material, and a thoriated filament at the smaller end, with a disc with fine perforation as anode. The fine cathode pencil passing through the pinhole, travels between two sets of plates at right angles, so that if two alternating P.D.'s from different parts of a circuit are connected to them, a trace in the form of a Lissajous figure is generally obtained. It is possible to show the hysteresis loop of an iron specimen directly in this manner.

The above type of oscillograph has the advantage of being permanently evacuated, but it is only suitable for the observation of certain cyclic phenomena, and does not permit of the photographic recording of intermittent or transient ones. Prof. Dufour in France and Dr. A. B. Wood in England, have therefore produced cathode ray oscillographs in which photographic plates can be inserted, and by using a cold cathode with a P.D. of 50,000 volts the former has obtained records of the wave form of radio transmitters up to over 1,000,000 ~ per second. Such oscillographs require to be evacuated after the removal of the camera or photographic plate, and not being hermetically sealed, are kept continuously evacuated during use.

Ammeters and Voltmeters.—As their names imply these instruments are respectively intended for directly measuring electric currents in amperes, and potential differences in volts, and they may conveniently be considered together as they are often similar in construction. For the majority of purposes these instruments are of the electromagnetic type, but thermal or "hot wire" instruments are used for alternating currents especially for those of high frequency such as are employed in radio working. The electromagnetic instruments are however of very diverse types. There are first (a) the moving magnet and (b) moving coil types corresponding to galvanometers; but in addition there are moving soft-iron dynamometer, and induction instruments, all of which can be used with alternating currents, the last being for alternating currents only.

Electromagnetic Instruments. (a) *Moving Magnet Type.*—The first direct reading ammeters and voltmeters introduced by Ayrton and Perry in 1879 were of this type. It consisted of a small magnetic needle on a short spindle between two pivots, and provided with an aluminium pointer. A small coil encircled the needle, and the whole system was fixed between the poles of a powerful permanent magnet, so that extraneous fields had little influence. The instrument has some similarity to the tangent galvanometer in principle, but the coil is small, and the earth's field is replaced by that of the horseshoe magnet. The large control given by such a magnet is an advantage in this case where sensitivity is ample, as it increases the rapidity of the readings. An interesting feature of this type of instrument was the winding of the coil with ten separate insulated strands which could be connected in series or parallel thus giving two ranges of a ten-fold ratio of current. The same type of instrument could be used as a voltmeter by winding the coil with fine copper wire and connecting it in series with a high resistance coil of German silver and other wire of low temperature coefficient so that its total resistance was sensibly constant, and the current flowing through it was proportional to the P.D. applied to the terminals of the instrument. This device can be employed with almost any type of ammeter. The moving magnet type of ammeter has gone out of use for many years owing to its cost, but it has recently been

revised in an interesting form by the Westinghouse company, who substitute a second horseshoe of nickel iron with its poles at right angles to those of the permanent magnet. This horseshoe projects through the back of the case, and the conductor carrying the current is simply threaded through it, so that the conductor need not be divided and the instrument has no terminals.

(b) *Moving Coil Permanent-magnet Indicating Instruments* were introduced by Dr. Weston in 1888 and were similar to the d'Arsonval galvanometer, except that the coil was pivoted and controlled by spiral springs carrying the current, and a pointer was substituted for the mirror. This type has been developed into the most accurate of all direct current indicating instruments in the Weston and other laboratory standards, and has assumed many different forms, notably the "Circscale" instruments of Messrs. Record, in which the poles are so arranged that the coil and pointer can rotate through nearly 270° . As the thin control springs can only carry a very small current (75 milliamperes is the usual maximum) the instrument can be used as a voltmeter by connecting a high resistance in series with the coil, but if it is to be employed for measuring larger currents, "shunts" are provided consisting of manganin or constantan strips having two terminals through which the current is passed, and two other terminals to which the instrument is connected, so that it acts as a low reading voltmeter measuring the current by the P.D. across the shunt. A single moving coil instrument with a set of series resistances and shunts will therefore serve for a very wide range of P.D. and current measurements, and portable "test sets" are commonly made covering the range from about 0.1 to 600 or more volts or amperes.

Moving Soft-iron Instruments.—These are the most simple and inexpensive ammeters and voltmeters and can be used both for direct and alternating current measurements. If a current is passed through a coil, a piece of soft iron will be sucked into it, and if a suitably shaped piece of soft iron is pivoted and provided with a pointer a very useful form of ammeter can be made. If the coil is wound with fine wire and a series resistance added the instrument becomes a voltmeter. The first instruments of this type were introduced by Ayrton and Perry in 1884 and others by Lord Kelvin, Schukert, Siemens, Nalder, Weston, etc. The last two are on what is called the repulsion principle, having two soft iron rods lying parallel to one another and to the axis of the coil. When the current flows these two rods are magnetized with the same polarities and consequently repel one another like the pith balls of an electroscope, so that if one is fixed and the other attached to a pivoted arm provided with a pointer, a deflection is produced. This last construction has some advantages over the others, as the two pieces of iron lie close together when the current is small, and are farther apart for large currents. For a given distance apart the force between the irons is proportional to the square of the current, so that it is very small for small currents, but this is partially compensated by their greater proximity, and the torque is consequently much more nearly proportional to the current and the instrument has a larger useful range than the single iron form. The same result may be obtained in the attraction forms by shaping the iron, but this requires careful experiment.

The moving soft-iron instruments are of great value in principle as they are not only simple in construction but are equally suitable for direct or alternating currents, as they obviously indicate the square root of mean square (R.M.S., or effective) current; while the moving coil permanent magnet instruments will only read on continuous current. Until quite recently, however, this valuable property was not taken full advantage of, owing to certain apparently inherent defects in the type. The first is the want of proportionality of magnetization in the iron to the current, and the hysteresis in the iron, which causes the instrument to read higher for a certain current when it has fallen from a higher value, than when it has risen from a lower one. In addition there is the high inductance of the coil with its iron cores, which causes a voltmeter of this type to read lower for the same P.D. as the frequency is increased and prevents the use of shunts for ammeters; and lastly, the demagnetizing effect of induced eddy currents in

the iron and any metal parts close to it. All these errors have militated against the adoption of this type as a universal instrument, although A.C. ammeters and voltmeters for a single frequency have been largely employed.

Within the last few years, however, a great advance has been made notably by the substitution of Permalloy or Mumetal for the moving iron, which has resulted in the practical elimination

BY COURTESY OF EDGCUMBE AND OCKENDON (INSTITUTION OF ELECTRICAL ENGINEERS)

FIG. 7.—PRECISION MOVING IRON INSTRUMENT

of wave form and hysteresis errors, and by making the coil as small and flat as possible so as to allow of a thin plate of this alloy to be attracted into it, thus greatly reducing the inductance and eddy-current errors. It was pointed out by Drysdale in 1924 that since the electromagnetic energy in an inductive coil $E = \frac{1}{2} Li^2$ where L is its inductance and i the current passing through it,

the torque $T = \frac{\partial E}{\partial \theta} = \frac{1}{2} i^2 \frac{\partial L}{\partial \theta}$, so that the instrument always oper-

ated by the increase of its inductance from L_0 at zero to L_{\max} at its highest reading; and he proposed the term "electromagnetic efficiency" for the fraction $(L_{\max} - L_0)/L_{\max}$. On examination of existing instruments it was found that this efficiency was only 1 or 2% or less, so that of the total inductance about 99% was useless and noxious, and only about 1% useful in deflecting the instrument. Acting on this principle Col. Edgcumbe and Mr. Ockenden devised an ammeter on the lines above indicated (fig. 7), with the result of obtaining practically negligible hysteresis and eddy current errors and of increasing the electromagnetic efficiency to about 30%, and the current range to 15 or 20 fold. This has enabled it to be employed with shunts or series resistances like the moving coil instruments, either for direct current or with alternating currents up to 200 periods per second. It is claimed, and with apparent justice, that such instruments need not be inferior in accuracy to moving coil or other high-grade instruments. By using one fixed and two independently moving irons, Record has produced a moving iron instrument having a scale covering about 270° .

Dynamometer Instruments.—These form an important class of current measuring instruments as they are equally suitable for direct or alternating currents, and can be made either as standard, sub-standard or deflectional indicating instruments.

BY PERMISSION OF KELVIN, BOTTOMLEY AND BAIRD

FIG. 8.—CONNECTIONS OF KELVIN AMPERE BALANCE

They depend fundamentally on Ampère's discovery (1820) that parallel conductors carrying currents attract each other if the currents are in the same direction or repel each other if they are in opposite directions. In 1843 Weber produced a simple form of "electrodynamometer" on this principle, but the first practical measuring instruments appeared in 1883, when Kelvin and Joule devised the standard current weigher or balance, and Siemens the substandard dynamometer.

The principle of the Kelvin balance is shown in fig. 8. The instrument consists essentially of six horizontal coils, four of which are fixed (F) and two movable (M), and the current to be measured traverses the whole of the coils in series. In order to allow the two movable coils to swing freely between the fixed ones, they are suspended by a large number of straight fine wires

forming straight straps or ligaments. The current passes round the coils as shown by the arrows, and it will be seen that on the right hand side the current in the centre moving coil is in the same direction as that in the upper and in the opposite direction to that in the lower of the fixed coils. The moving coil is therefore attracted to the upper and repelled from the lower coil and tends to move upwards, while the left hand moving coil in which the current circulates in the opposite direction tends to move downwards. The whole moving coil system therefore cants upwards at its right hand end, and can be brought back to the level or zero position by a weight hung at that end. To simplify the measurement the moving coils are mounted in a light frame having a long bar and scale in front, along which a weight can slide as in a steelyard balance and this is operated by a silk cord passing through the ends of the cover and provided with a device for freeing the cord from the weight when the latter is in position. Each balance has four weights for obtaining different ranges.

The electromagnetic potential energy of two circuits traversed by currents i_1 and i_2 and having a coefficient of mutual inductance M with one another is Mi_1i_2 , so that the torque developed is

$i_1i_2 \frac{\partial M}{\partial \theta}$. In the Kelvin balance the two circuits are in series so

that $i_1 = i_2 = i$, and the torque is $i^2 \frac{\partial M}{\partial \theta}$, or is proportional to the

square of the current, so that the instrument serves equally for direct or alternating current measurements. Various sizes of these balances, "Centiampere," "Ampere," "Deka-Ampere," "Hector-Ampere," and "Kilo-Ampere" have been constructed, but the latter, on account of their large conductors, are not accurate for high frequency currents owing to eddy currents, although the conductors are laminated.

The Siemens dynamometer (fig. 9) was for many years the most useful form of substandard instrument for both direct and alternating current testing. It consists essentially of two coils at right angles, the inner (F) having a large number of turns and being fixed with its axis horizontal on a wooden frame, and the outer (D) in the form of a loop encircling the fixed coil and suspended by a silk thread, with its two ends brought out at the bottom to dip into two mercury cups MM. On the top of the frame a circular scale is fixed, with a torsion head T and pointer,

BY PERMISSION OF SIEMENS, LTD.

FIG. 9.—SIEMENS ELECTRODYNAMOMETER

a cylindrical spring S encircling the suspension being mounted between the torsion head and the top of the coil. The current circulates round both coils in series and causes the swinging coil to turn, whereupon the torsion head is turned until the torsion of the spring brings the coil back to its zero position as indicated by a pointer I fixed to the top of the coil. The current then $= K\sqrt{D}$, where K is the constant of the instrument and D the angle turned by the torsion head. In order to increase the range of the instrument, the fixed coil is generally made of two portions with different thicknesses and number of turns of wire, and either of

these can be connected in series with the moving coil.

Both of the above instruments are of the standard type in which it is necessary always to bring the coils into the same position, in order that the theoretical square law shall be followed. But deflectional direct indicating instruments can be made by simply providing the moving coil with a pointer and control spring, in which case they are equivalent to permanent magnet moving coil instruments in which the magnet is replaced by the fixed coil. In 1890 the first instrument of this type was introduced by Dr. Weston as a dynamometer voltmeter, the fixed and moving coils being circular, wound with fine wire, and connected in series through the spiral springs which provided the control. A high non-inductive resistance was connected in series with the combination and the instrument was graduated as a direct reading voltmeter. Additional ranges were provided by extra series resistances. Dynamometer ammeters have also been constructed by making the fixed coil of thicker wire and connecting the moving coil in series with a small non-inductive resistance across the terminals of the fixed coil or an additional shunt, but it is difficult to eliminate inductive errors sufficiently in such instruments.

The most valuable application of the dynamometer principle is to standard and deflectional wattmeters, and to energy meters, which will be described later.

Induction Instruments.—These instruments may be described as dynamometer instruments in which current is led into the moving system by induction or transformer action instead of by conduction through springs or ligaments, and they can therefore only be used for alternating currents. They were initiated by Prof. Ferraris, the pioneer of polyphase working, in 1885, but have assumed many different forms, and have been adapted for many different measurements.

Induction instruments may be divided into three main classes, (a) repulsion, (b) shaded pole and (c) double pole instruments. The first depend upon the repulsion effect first discovered by Prof. Elihu Thomson, that a metal disc or ring is repelled from an electromagnet excited by alternating current. The explanation is that the magnet induces an e.m.f. in the disc or ring in quadrature with the magnetic field, which consequently produces eddy currents in it. If these currents were in phase with the induced e.m.f. they would also be in quadrature with the magnetic field and there would be no resultant force, but owing to the inductance and low resistance of the disc they lag behind the e.m.f. and become somewhat in antiphase with the magnetic field, producing a resultant repulsion.

The simplest application of this principle to ammeters is that of the Westinghouse company, in which the moving element consists simply of a thin aluminium or copper disc on a pivoted spindle perpendicular to its plane. The edge of this disc is however cut in the form of a cam and can turn in the gap of a laminated electromagnet through the coil of which the alternating current to be measured is passed. A control spring and pointer is attached to the spindle and when the system is at zero the whole of the pole face is covered by the disc. When the current is passed the repulsion effect causes the disc to turn so that less of the pole face is covered by the disc, and by suitably shaping the edge a long and fairly even scale can be obtained. In order to damp the swinging of the disc, a permanent magnet is mounted on the other side of it, which retards its movements by the eddy currents induced.

The shaded pole type of instrument is next in simplicity of construction, but is best understood by first describing the double pole form. If two laminated electromagnets A and B are fixed close together and act on a single circular disc, the alternating magnetism of A induces currents in the disc part of which pass through the gap of magnet B, so that the disc behaves as a moving coil carrying current derived from A and traversing the magnetic field of B, and thus producing a torque. But, reciprocally, the currents induced in the disc by magnet B traverse the field of A, and it is fairly obvious from the symmetry of the arrangement that if the two magnetic fields vary in the same phase, there will be no resultant torque, as there is no reason why it should move from A to B rather than from B to A. But if the magnetic

field in B lags in phase behind that of A there is a resultant torque from A to B and this torque is proportional to $i_1 i_2 \sin \phi$ where i_1 and i_2 are the currents in the two coils and ϕ the angle of phase difference between the fields. This difference in phase may be secured in several ways, e.g., by shunting one of the magnets or connecting it in series with a condenser, or by supplying the currents from different parts of the circuit, as will be described under wattmeters and energy meters.

The most simple application of this principle however to current measuring instruments is by "shading" part of a single pole (fig. 10). If a single laminated electromagnet has a cleft in its pole and a thick copper ring C encircles one part of it, B as shown, the eddy currents induced in this ring by the magnet react on its field and cause the magnetism of the part of the pole encircled by the ring, or "shaded" portion, to lag behind that of the remainder or unshaded portion A. Thus the single magnet behaves like the two magnets above referred to, and a pivoted disc arranged in the field of this magnet tends to turn from A to B. By adding a spring and pointer and damping magnet, a useful form of ammeter can be produced, and the scale can be of any length up to nearly 360° . The theory of induction instruments is very complex, and they are liable to many errors, but by careful design they may be made very useful and accurate instruments.

FIG. 10

Current and P.D. Transformers.—A great difficulty with alternating current instruments is their lack of range, as since the forces in them are generally proportional to the square of the current, a reduction of the current to one-third reduces the force to one-ninth of its maximum value, and many instruments therefore only have about a fourfold useful range. On the other hand, the range of currents and voltages to be measured is enormous, from fractions to tens of thousands of amperes or volts. With nearly all such instruments shunts are useless owing to the induction errors they introduce, and for many years past the practice of employing transformers has been adopted. If a transformer is made with a good well-laminated magnetic circuit and two coils wound close together, one of which is short circuited through an ammeter, while the other has the alternating current to be measured passed through it, the current induced in the secondary coil will be proportional to that in the primary coil and approximately in the ratio of the number of turns in the coils. For example if an alternating current of 5,000 amperes is to be measured, a transformer may be made with a single bar or turn carrying this current, and a secondary coil of 1,000 turns which is connected to a 5 ampere ammeter. This device has the further important advantage of isolating the ammeter completely from the main circuit, which may be at a dangerously high potential on modern supply circuits. In like manner, if a transformer is wound with two coils of fine wire, one having 100 times as many turns as the other, and an alternating P.D. of 10,000 volts is applied to the coil having the larger number of turns, it will induce 100 volts in the other coil which can be measured in an ordinary voltmeter, without connecting it to the high voltage circuit. By the use of the Mumetal for the iron of the transformers, Col. Edgcumbe and Mr. Ockenden have recently made instrument transformers of very high precision.

Thermal or Hot Wire Instruments.—These instruments, as has been mentioned, depend upon the heating effect of a current passing through a conductor, and are equally suitable for direct or alternating current measurement. The power developed in a circuit having a resistance r ohms and carrying a current i amperes is ri^2 watts, and produces a heating effect of $0.24 ri^2$ calories per second. Since the heating is proportional to the square of the current, it is the same for either direction of flow, and the average heating with alternating current is proportional to the mean square of the current.

Hot wire instruments are of two types (a) expansion and (b) thermo-junction. In the former the linear expansion of the wire caused by the heating is utilized; in the latter the heat is communicated to a thermo junction, which is connected to a millivoltmeter.

Until the last few years hot wire instruments have all been on the expansion principle, the earliest form being the voltmeter, devised by Maj. Cardew in 1883. In this instrument a long thin platinum-silver wire was strung over pulleys in a brass tube, and the ends of the wire were connected to the terminals; while the pointer was mounted on a spindle geared to a pulley which was turned by a thin strip. One end of this strip was attached to the axle of a pulley at the centre of the wire and the other, through a cylindrical spring, to a fixed support. When current passed through the wire, causing heating and expansion, it yielded to the tension of the spring and caused the pointer to turn; while when the current was broken, the wire contracted and pulled the pointer back to zero.

This form of voltmeter was very clumsy and inconvenient and wasteful of power, but its freedom from inductance was such a valuable feature as to stimulate improvements, and modern hot wire instruments have been constructed on the "sag" principle originally suggested by Ayrton and Perry, but first carried into execution by Hartmann and Braun. In these instruments the heated wire is straight and only a few inches long, and both ends are fixed; but the strip attached to the pointer and antagonistic spring is attached near the centre of the wire, so that the tension tends to pull it to one side or cause it to sag. A very small increase of the length of the wire will greatly increase this sag, and approximately as the square root of the extension, so that not only does this method give a large magnification, but it helps to compensate for the natural square law of the expansion, and gives a more uniform scale. The magnification secured by a single application of this principle was, however, hardly sufficient, so that in the Hartmann and Braun instrument (fig. 11) the transverse wire S_2 was again treated as a sagging wire and the strip actuating the pointer was attached to its centre, making it what may be called a double-sag instrument. A thin aluminium sector passing between the poles of a permanent magnet served to damp the indication. An average instrument of this type takes about 0.2 ampere at its maximum reading and has a resistance of about 17 ohms, implying a power consumption of 0.7 watt in the wire; but when used as a voltmeter for 120 volts it consumes a total of 24 watts, as compared with only 4 or 5 watts for moving iron voltmeters. To adapt this type of instrument as an ammeter, one method is to lead the current in and out of the wire at several points by means of very thin and flexible strips S_1 and S_3 . If the current is led in at the centre of the wire and out by its two ends the range is doubled, and so on. For still heavier currents a large number of exactly similar wires can be connected in parallel, and shunts can also be employed.

FIG. 11.—HARTMANN AND BRAUN'S AMMETER

Expansion instruments have done valuable service for alternating current measurements, especially at high frequencies, but they have never attained the accuracy of good electromagnetic instruments, owing to the changes of zero due to expansion of the supports. Various methods of compensation have been devised with good results, but none have been completely satisfactory under all conditions. Another objection to them is their very small overload capacity, as the wire must be raised to a high temperature to obtain sufficient expansion. Doubling the current produces four times the heating effect. Fusing of the working wire involves remounting and recalibration of the instrument.

The thermo-junction instruments which were first put into commercial form by the Weston company are much more convenient than the expansion type, and are probably destined to supersede it, as they only involve a simple attachment to a stand-

ard type of moving coil millivoltmeter. For many years before their advent a very common laboratory device for measuring high frequency currents was the "crossed thermo-junction," consisting of two fine wires, one of copper and the other of constantan (nickel-copper alloy) crossed at right angles and soldered together at their crossing point. Current was passed from one end of the copper wire through the junction to one end of the constantan wire, causing the junction to be heated; while the other two ends were connected to a moving coil galvanometer. As the thermo e.m.f. of such a junction is about 40 microvolts per degree, a rise of 300° C produces an e.m.f. of 12 millivolts, which will produce a reasonable deflection on a moving-coil pointer instrument. The Weston company therefore employed one of their standard forms of moving coil millivoltmeter with a recess in the base in which a strip carrying a short heating wire and thermo-junction was clamped. This can be easily replaced if burnt out.

Dr. Moll has recently greatly improved on this device by what he calls his "thermo-converter," having a fairly long heating wire threaded through about 50 insulated thermo junctions. By this means he secures a thermo e.m.f. of 8.5 millivolts for 16 milliamperes in the heating wire and a rise of temperature of only 10° C, which allows a very ample margin for overload.

III. POWER AND ENERGY MEASUREMENT

Wattmeters are intended for the direct measurement of electrical power, especially in alternating current circuits. As the power expended in, or taken from, an electrical circuit, in watts, is equal to the product of the P.D. in volts and current in amperes, it can be measured on direct-current circuits by a voltmeter and ammeter. But with alternating or pulsating currents this is not the case, and a special instrument is needed in which the torque is proportional to the product of the P.D. and current *at each instant*, and indicates the mean value. Such instruments are termed wattmeters and are essential for all alternating current power measurements. They may be either electromagnetic, electrostatic, or thermal, but practically all indicating wattmeters are on the electromagnetic principle, and most are of the dynamometer type. It has been stated above that if two current carrying coils are near together, the force or deflecting torque between them is proportional to the product of the strengths of the two currents, so that if one of the coils carries the current in the circuit by being connected in series with it, and the other is wound with fine wire and shunted across the circuit like a voltmeter, the current in the second coil is proportional to the P.D. if its resistance is constant, and the force or torque between the coils is proportional to the product of the P.D. and current, *i.e.*, to the power in the circuit, at each instant. If the shunt coil is suspended inside the series coil and provided with a pointer and control spring the deflection is proportional to the average power, as the inertia of the coil prevents it from following the rapid variations of the alternating currents.

The principle of the electro-dynamometer wattmeter was first put forward by Ayrton and Perry in 1881, and was adopted by Kelvin in his Watt balance, and by Siemens in 1884, the moving coils of the Kelvin balance or Siemens dynamometer being made of fine wire and in series with non-inductive resistances. Unfortunately, Ayrton and Perry, from a theoretical consideration of its behaviour on alternating current circuits at various

power factors, were led to the conclusion that large and indeterminate errors would appear at low power factors (*i.e.*, large angles of lag or lead of the current), and as this was apparently confirmed by some tests with a defectively constructed wattmeter of Swinburne's, the dynamometer wattmeter fell into disrepute. It was not till 1901, when Drysdale gave a different treatment of the errors, and showed that they could be made perfectly determinate, and be reduced to inappreciable proportions by suitable design, that confidence was restored. He showed that if the ratio of resistance to inductance of the shunt circuit was over 300 ohms per millihenry, and if the instrument was kept free from metal other than the carefully stranded coils, no readable error could exist, and produced a wattmeter in which these requirements were fulfilled. A little later Duddell and Mather produced an astatic wattmeter on very similar lines. Both of these instruments were of the torsional or standard type, and their current ranges could be varied by combining the strands of the current coils in various series and parallel combinations, while the P.D. range could be extended to almost any extent by series resistances.

Deflectional direct reading dynamometer wattmeters have been devised by Kelvin, Heap, Hartmann and Braun, the Weston Instrument Company, and many others, and are similar to the corresponding forms of dynamometer voltmeters, but with the fixed coils wound with thick wire to carry the current. The Weston wattmeter has a circular formerless moving coil fixed on a pivoted spindle with two spiral springs serving as control and leading-in wires, and a light truss-form pointer at the upper end, and damping vanes at the lower end. Two fixed current coils are held in a frame of high resistance metal alloy to reduce eddy currents, and the moving coil swings inside them over an arc of about 90°.

The quadrant electrometer can also be used as a wattmeter since the deflection is proportional to the product of the P.D. between the quadrants and of that between the needle and the mean of the quadrants or to $(V_2 - V_1) \left(V - \frac{V_1 + V_2}{2} \right)$ where V , V_1 and V_2 are the potentials of the needles and of the two quadrants respectively. If a non-inductive resistance r is connected across the quadrants and the current i is passed through it $V_2 - V_1 = ri$ or is proportional to the current, and if the P.D. is applied between the midpoint of this resistance and the needle, the deflection is proportional to the product of the current and P.D., *i.e.*, to the power. This electrostatic method was also devised by Ayrton and Perry, and was developed about 1900 by Addenbrook and later by Paterson and Rayner at the National Physical Laboratory, where it is used as the standard for checking commercial wattmeters. It is not, however, suitable for portable or switchboard instruments owing to the small forces available. Thermal or hot wire wattmeters have also been devised by Field, Irwin, and others but have not come into general use.

The induction type of instrument however lends itself excellently to switchboard wattmeters of moderate accuracy owing to the simplicity and robustness of its construction. In discussing the double magnet induction ammeter (*q.v.*) it is stated that the torque on the disc is proportional to $i_1 i_2 \sin \theta$ where i_1 and i_2 are the currents in the coils and θ the angle of phase difference between them. If one of the magnets is wound with thick wire and connected in series with the circuit like an ammeter, and the other is wound with fine wire and connected across the mains like a voltmeter, the current in the latter coil is proportional to the P.D. across the mains but nearly in quadrature with it owing to its high inductance so that $\sin \theta = \cos \theta$ where θ is the phase difference between the circuit P.D. and current. The torque is therefore proportional to $Vi \cos \theta$ *i.e.*, to the power. Certain compensations are necessary, as the resistance of the shunt coil destroys the perfect quadrature, but they can be effected with sufficient accuracy, and if the disc is provided with a damping magnet and control spring a long scale indicating wattmeter with proportional scale is produced. A large number of such wattmeters have been devised and Edgcumbe and Ockenden, and Lipman have recently carried the design to great perfection. On the other hand if the control spring is removed, the torque developed by the damping magnet is proportional to the speed, and as it is

FIG. 12.—ELECTRIC SUPPLY METER

also proportional to the power, the disc will rotate at a uniform speed proportional to the power. The amount of the rotation in a given time will thus be proportional to the time integral of the power, or to the total energy supplied or absorbed. The instrument then becomes an energy supply meter, and the bulk of the supply meters used on A.C. circuits to-day are on this principle.

Polyphase Wattmeters.—About 1896 Dobrowolski pointed out that the power either on a two phase supply or on a three phase three wire supply could be obtained by using two wattmeters and adding their readings together. Following on this, Drysdale in 1901 produced a double wattmeter with two similar moving coils at right angles, one below the other, on the same spindle, and with two similar sets of stranded fixed coils also at right angles, so that the indications of the two systems were mechanically added together on the spindle and could be balanced by torsion in the usual manner. Deflectional direct reading polyphase wattmeters have since been made on this principle by the Weston Instrument company, and many others. The induction wattmeter and energy meter can similarly be adapted for polyphase supplies, by using two sets of series and shunt magnets on opposite sides of the same disc.

Electric Supply Meters.—These meters are used for indicating the total energy supplied to a consumer or from a generating station and are, therefore, used in large numbers, and have assumed a great variety of forms. There are two chief classes, "quantity" or "ampere-hour" meters, and "energy" meters, both of which are in vogue. The power developed by or given to a circuit in watts at any instant is $W = VI$, or in kilowatts

$KW = \frac{VI}{1000}$, and the energy in kilowatt-hours or Board of

Trade Units (B.T.U.) is therefore $\frac{VI t}{1000}$ where t is the time of supply in hours, if V and I are constant over the time, or $\frac{1}{1000} \int_0^t V I dt = \frac{1}{1000} \int_0^t W dt$ if they vary. An energy meter may be called an integrating wattmeter; but since most electrical supplies are at an approximately constant voltage $\int_0^t V I dt = V \int_0^t I dt$, and it is sufficient to measure $\int_0^t I dt$ or the total "quantity" in ampere hours; hence the above names.

Quantity meters are obviously the more simple, as they do not require to take the P.D. into account; and the most simple of all are those on the voltameter or electrolytic principle. The weight of metal deposited or volume of gas liberated in an electrolytic cell is proportional to the quantity of electricity passing. The first supply meter invented by Edison in 1879 was of this type and employed zinc plates in zinc sulphate solution. Bastian in 1898 produced a meter on the water voltameter principle, consisting of a glass vessel containing two electrodes through which the current passed causing the evolution of hydrogen and oxygen and the descent of the level of the water, which was indicated by a scale on the side of the vessel. The only electrolytic meter, however, which has proved satisfactory in service is the mercury meter of Wright in which mercury is deposited from a solution of mercurous nitrate (later a mixture of mercury, sodium and hydrogen chlorates) and drops into a graduated tube which

FROM GLAZEBROOK, "DICTIONARY OF APPLIED PHYSICS" (MACMILLAN)
FIG. 13.—OHMMETER: A & B, COILS; R, RESISTANCE; V, BATTERY; X, UNKNOWN RESISTANCE

FIG. 14.—MOTOR METER

siphons over when full into a larger graduated tube. The whole apparatus is sealed and hinged in a case, so that when both tubes are full it can be filled up and the mercury repeats its course.

Motor Meters.—The majority of supply meters now in use are on the motor principle in which the current or power supply causes a moving element to rotate against some form of brake so that its speed is proportional to the current or power and the total rotation in any time indicates the quantity in ampere hours or the energy in kilowatt hours (Board of Trade Units or B.T.U.). Fundamentally there are two types of such meters, those in which the driving torque is proportional to the current or power and the braking torque to the speed, and those in which the driving torque is proportional to the square of the current and the braking torque to the square of the speed. The great majority of meters in present use, however, are of the former type, and the first practical suggestion of an energy meter on such lines was made by Ayrton and Perry in 1882. It may be briefly described as a rotating or integrating wattmeter in which the swinging moving coil is replaced by an armature, commutator and brushes, the former being wound with fine wire and connected in series with a high resistance across the mains; while the fixed current coil is connected like an ammeter in series with one main. When current passes through both coils a torque is produced which is proportional to the product of the two currents or to the product of the P.D. and main current, *i.e.*, the power. In the ordinary moving coil instrument the coil only deflects through a definite angle but the commutator rotating between the brushes brings new coils into the field and tends to produce a continuous rotation which is secured by removing the control and using a copper disc with permanent magnet as a brake, and a counting train to register the revolutions or B.T.U. Prof. Elihu Thomson developed this into a successful supply meter which is still used for direct currents, and could also be used for alternating current supply, but has been almost superseded for the latter purpose by the induction energy meter based on the induction wattmeter already described. Many attempts have been made at improving the commutator motor meter, especially as regards diminishing the friction of the brushes, which tends to cause it to stick or under register at low loads; the most successful being the "frictionless" motor meter of S. Evershed, in which the commutator strips are in the form of elastic springs rotating between "brushes" in the form of friction wheels. The greater part of the weight of the moving system is compensated by a permanent magnet attracting the top of the spindle, and the movements are communicated to the counting train magnetically, instead of by direct coupling. Unfortunately the cost of this meter prevents its general use, but it stands as the highest achievement in the supply meter field.

By substituting a permanent magnet for the fixed coils in the motor energy meter and passing the main current, or a fixed fraction of it derived from a shunt, through the armature, a more simple and robust form of meter can be constructed, owing to the more intense field of the magnet; but the meter then becomes a quantity meter suitable for direct currents only. This type has been developed by the Bat Meter company and others and by the British Thomson Houston company for use on electric cars. The chief difficulty as regards the satisfactory performance of the above motors is, as has been above said, the brush friction; and, therefore, several types of quantity meter have been developed by Chamberlain and Hookham, Prof. Perry, and Messrs. Ferranti, etc., in which the armature is reduced to a pool of mercury or to a metal disc floating in it. These meters are practically always of the quantity type with a permanent magnet or electromagnet field, and the current flows through the mercury either from its centre to its circumference, across its diameter or axially. Whenever it happens that the magnet is permanent, its field is constant, and the torque is proportional to the current, in which case the braking is effected by the

FIG. 15.—WHEATSTONE BRIDGE

eddy currents induced by the magnet; but when it is an electromagnet in series with the mercury the torque is approximately proportional to the square of the current, and the braking is effected by roughening the inside of the mercury container, in which case the braking torque at high speeds is proportional to the square of the speed. The meter may be used with alternating currents, but the inductance of its magnet is generally too high.

Of alternating current motor meters by far the most generally

FROM GLAZEBROOK, "DICTIONARY OF APPLIED PHYSICS" (MACMILLAN)

FIG. 16.—IMPROVED WHEATSTONE BRIDGE TO ELIMINATE CONTACT RESISTANCE OF A NUMBER OF PLUGS

useful at the present time is the induction energy meter which has assumed a great variety of forms, most of which give a good performance. As above described, the induction wattmeter consisted simply of an aluminium disc between the poles of two adjacent laminated electromagnets, one of which was wound with thick wire which carried the main current, while the other was wound with fine wire and connected across the mains. The torque tending to rotate the disc is then proportional to the power in watts and if the control spring is removed, and a permanent magnet brake is employed, the speed of rotation of the disc is proportional to the power, and the total rotation in a given time is proportional to the total energy supplied during that time, which is registered by a counting train geared to the spindle of the disc. The first purely alternating current motor meter, however, was the quantity meter of Schallenger, in which a light aluminium disc was pivoted on a spindle through its centre, and turned in the field of two main coils. Inside these coils, was a number of flat copper strips slotted in the centre to allow the disc to pass through, and set at an angle of about 45° with the main coils. These strips, therefore, acted as short circuited coils through which a portion of the main field passed and induced lagging currents in them, so that the whole arrangement acted as a crude two-phase or rotating field motor in which the disc was carried round by induction. As the driving torque was proportional to the square of the current, as in the dynamometer ammeter, the braking torque had to be proportional to the square of the speed, which was effected by having four damping vanes revolving at high speed in the air. An even more simple A.C. motor meter was devised by Prof. George Forbes on the hot wire principle, the current passing through a horizontal spiral ring of resistance wire and causing hot air currents to rise from it and turn a light windmill, which provided its own braking torque. Clock meters, which were also originally devised by Ayrton and Perry in 1882, and which were developed to an extraordinary extent by Dr. Aron, have had a considerable amount of popularity owing to their great adaptability, but are now almost superseded. If an ordinary pendulum of length L is allowed to swing freely, its periodic time $t = 2\pi\sqrt{\frac{L}{G}}$ where G is the constant acceleration of gravity, and its frequency of oscillation is therefore $n = \frac{1}{2\pi}\sqrt{\frac{G}{L}}$. If G can be effectively increased by attracting the bob by a magnet or coil to some value $(G+g)$, the frequency n will be increased to $n' = \frac{1}{2\pi}\sqrt{\frac{G+g}{L}} = \frac{1}{2\pi}\left(1 + \frac{g}{G}\right)\sqrt{\frac{G}{L}}$ approximately, so that the increase of frequency or rate of the pendulum $= (n' - n) = \left(\frac{1}{4\pi\sqrt{GL}}\right)g$, or is proportional to the at-

traction g . If, therefore, two clocks are mounted side by side with exactly similar pendulums, and one is attracted, this one will gain on the other, and the difference of time indicated by the two clocks will be proportional to $\int_0^t g dt$. If the pendulum bob is a permanent magnet swinging over a coil traversed by the main current, i , g is proportional to i and the difference of time is proportional to $\int_0^t i dt$ or to Q , so that we have a direct current quantity meter. If a fine wire shunt coil is fixed on the pendulum and swings over the current coil, g is proportional to \sqrt{i} so that the gain of rate is proportional to $\int_0^t \sqrt{i} dt$ or to the energy, and this is applicable either to direct or alternating currents. By coupling the two clocks together by differential gear, by arranging one pendulum to be attracted and the other repelled, and by other ingenious devices, Dr. Aron produced fairly accurate supply meters, and meters on this principle have also been devised by Féry and others.

Lastly, we have had a very large variety of continuous and intermittent integrating meters with very ingenious mechanisms, of which the Frager meter was the pioneer; and also, in recent times prepayment meters of both the electrolytic and motor types, in which the insertion of a coin switches on the current and releases the mechanism until a certain amount of quantity or energy has passed when the latter first breaks a switch shunted by a resistance so that the lights are dimmed as a warning, and breaks entirely later, if the warning is disregarded. The growing practice of inducing consumers to keep their maximum call on the supply as little as possible above their average demand, by charging according to the latter, has involved the introduction of a maximum demand indicator, usually as a separate adjunct to the meter.

IV. RESISTANCE MEASURING INSTRUMENTS

The majority of instruments for electrical resistance measurement are of the comparison type, and only a few give direct indications on a dial. Taking the latter first, these are generally known as ohmmeters from the original instrument of Ayrton and Perry, but as they are used in great numbers for insulation testing, trade names such as "Megger," "Ohmer," "Omega," "Metrohm," etc., are in vogue. Their fundamental principle is

based on Ohm's law, which may be written in the form $R = \frac{V}{i}$, so that if we could produce an instrument the indications of which are proportional to the ratio of P.D. to current, it would indicate resistance directly. In dealing with the Wattmeter it was shown that if two coils are at right angles, one carrying the current and the other connected as a shunt to the circuit, the torque between them was proportional to the product Vi , but if both coils are fixed and a magnetic needle is pivoted at their centre it will set itself along the resultant magnetic field of the two coils (neglecting for the moment the earth's magnetic field). If one coil is connected in series with the circuit it will carry the current i and produce a magnetic field H_1 proportional to i , while if the other is wound with very fine wire and connected as a shunt to the mains it will carry a current proportional to the P.D. V and producing a magnetic field H_2 proportional to V and at right angles to H_1 . The instrument therefore acts as a tangent galvanometer in which the field H_2 is substituted for the earth's field, and $\tan \theta = \frac{H_2}{H_1}$ is proportional to $\frac{V}{i}$ or to R . It is readily seen that variation of the P.D. of the mains does not affect the deflection, as if it is doubled both H_2 and H_1 are doubled and their resultant maintains the same direction. The effect of the earth's field can of course be eliminated by making the system astatic with one needle outside the coils.

The great use of this instrument has been the testing of insulation resistance, in which R may amount to many millions of ohms (megohms), so that in order to get a good testing current the P.D. V must amount to a few hundred volts. This is the more

desirable as a circuit may show a high insulation resistance with a few volts, but break down with a large P.D.; and it is therefore important to make the test with at least twice the P.D. the circuit is intended for. As the chief object of the ohmmeter is testing in situ; and as high voltage batteries are heavy and clumsy, their place is taken by a hand magneto generator which generates the required P.D. of say 250 or 500 volts or more by turning an armature in the field of a permanent magnet by means of a handle and gearing.

In the more recent Evershed "Megger" and some other instruments the moving needle system is replaced by a permanent magnet moving coil system with two moving coils (current and P.D.) on the same spindle. The same magnet is sometimes employed to produce the field for the moving coils and for the generator, the whole of the apparatus being in a single case with the handle and gearing with a slipping clutch for obtaining approximately constant speed and P.D. at one end, and the ohmmeter movement at the other. By shunting the series coil, a lower range is obtainable for low insulations, and the device may be made capable of measuring resistances of a fraction of an ohm. The Cox-Nalder "Ohmer" is on a somewhat similar electrostatic principle, but the double moving coil is the most common.

Resistance Boxes and Wheatstone Bridges.—The most accurate method of measuring resistance is by comparison with a known resistance, and for this and other purposes, boxes of accurately adjusted resistances with convenient arrangements for connecting any number of them in series are largely employed. Two types in use are the plug and sliding-contact types. In the former, the resistance coils are connected between brass blocks, and plugs with ebonite tops are provided which on insertion into the tapered holes between the blocks short circuit the respective coils, so that the total resistance between the terminals is the sum of the resistances of the coils unplugged. A common arrangement of the coils in this case is 0.1, 0.2, 0.3, 0.4; 1, 2, 3, 4; 10, 20, 30, 40, etc., ohms, so that any value up to the maximum can be obtained in steps of 0.1 ohm. An alternative and more convenient arrangement is a dial form, which has one central block with eleven others surrounding it, any one of which can be plugged into contact with the central one. In this case ten coils of equal resistance are used connected between successive outer blocks as shown, and the resistance in each dial is then indicated by the figure on the block in which the plug stands.

The sliding contact type is always of the dial form and is equivalent to that just described except that contact is made between the central and outer blocks by a well laminated copper brush which slides over the blocks. In the best types a spring "click" is also provided which slips into notches in a steel plate as the brush passes the centre of each block, so as to avoid the necessity for observing whether it is in position. The sliding contact form is more convenient and rapid in use, but not so accurate as the plug form. The resistance of a good plug contact is only about 50 microhms, while that of brush contacts is from 160 to 500 microhms or more, though Messrs. Tinsley have recently introduced a new form for which they claim a constancy of contact resistance of about 20 microhms.

The construction and adjustment of the resistance coils demands considerable care. The wire is now almost universally of Manganin (Cu 84, Mn 12, Ni 4 with a trace of iron) discovered by Dr. Weston in 1889 and largely used by St. Lindeck. This combines high specific resistance (about 50 microhms per cm. cube) with extremely low temperature variation, and low thermo e.m.f. to copper. A length of silk covered wire of approximately the required resistance is first doubled on itself and wound on a short length of brass tube which has previously been wound over with silk tape and varnished with shellac varnish. After winding and securing the coil in place with silk thread it is varnished and baked for some hours at a temperature of 140° C to

anneal it, and after cooling its resistance is carefully measured on a Wheatstone bridge with knife edge clips which allow the wire to be pushed through until the exact resistance is obtained. Small copper washers are then silver-soldered to the ends of the wire, and the finished coils are then screwed into position on the box and the washers screwed up and soft-soldered on the screwed lugs from the blocks. After this the whole box should if possible be stored for several months to allow the coils to settle down in resistance, and exact adjustment is then effected by scraping the wires near to the terminals. The hollow brass tubes have holes drilled near their attachment to the base so that they are open top and bottom, and allow of air circulating through them when the coil is heated by a current. Other forms of coil are in use for very high frequency work, but the great majority are now constructed much as above described.

For the measurement and adjustment of resistances, except of very low values, the Wheatstone bridge is the most convenient and commonly used device. It consists essentially of a resistance box of any one of the above types to which is added a set of "ratio coils" which enable its resistance to be balanced or compared with any unknown resistance.

Resistance standards of 0.1 ohm or less are usually provided with four terminals, two for the passage of the current, and the other two for enabling the P.D. to be tapped off. For the measurement of such currents the Kelvin double bridge having two sets of ratio coils is used. Many special forms of bridge have been devised for the accurate comparison of standard resistances of which the best known are those of Carey-Foster, Fleming, F. E. Smith and Drysdale. The two latter enable either two or four terminal resistances to be compared to an accuracy of within one part in a million.

V. POTENTIAL MEASURING INSTRUMENTS

Direct Current Potentiometers.—The potentiometer is the most generally useful of all accurate electrical instruments. As its name implies its primary function is the measurement of potential differences, but it is equally applicable for the measurement of currents of any value, when a few suitable resistance standards are available. Its fundamental principle is derived from a method devised by Poggendorf for comparing the e.m.f.s. of two cells and consists in employing a long uniform wire through which a steady current is kept flowing and in which consequently there is a uniform fall of potential from one end to the other (fig. 20). If r is the resistance of the wire per unit length and i the current flowing through it, the fall of potential per unit length is ri , so that the P.D. between any two points on the wire is $V = ril$ where l is the distance between them. If, then, a cell having a known e.m.f. E_1 is connected in series with a galvanometer to two contacts on the wire, and one of them is moved until the galvanometer is at zero, indicating that no current is flowing, then $E_1 = ril_1$. On substituting another cell of unknown e.m.f., E_2 , and moving the contact until balance is again obtained, $E_2 = ril_2$, so that if the current in the wire has kept constant during the whole process

$$\frac{E_2}{E_1} = \frac{l_2}{l_1} \quad \text{or} \quad E_2 = \frac{l_2}{l_1} E_1.$$

The method is analogous to weighing by a steelyard with sliding weight.

If the wire is made of a definite resistance, say 2 ohms for a length of a metre, and is traversed by a current of 0.05 ampere, then the total P.D. for 100 cm. is 0.1 volt or 0.001 volt per millimetre. Further, if at one end of this wire any number of resistances each of 2 ohms are connected in series, each of them will have a P.D. of 0.1 volt, which can be added to that of any section of the wire, as additional weights to a steelyard. This is the basis of the first accurate form of potentiometer devised by Prof. J. A. Fleming in 1885, and practically developed by Crompton. It consists of a rectangular base carrying the slidewire in front, the dial of 14 extra coils on the left, coarse and fine rheostats R for adjusting the current in the centre, and a selector switch, which enables the sliding contacts and galvanometer G to be connected to a number of different cells or circuits to be tested. The

FIG. 17.—POTENTIOMETER

main current is supplied from a 2 volt secondary cell, B, and it is adjusted by the aid of a standard cell C. If this cell is a Cadmium cell (*q.v.*), having an e.m.f. of 1.0183 volts, the potentiometer contacts are set to 10 on the dial (= 1 volt) and 18.3 divisions on the slide wire, and the rheostats adjusted till balance is obtained. The potentiometer is then ready for use, and will measure any P.D. up to 1.5 volts directly. Higher P.D.'s up to 600 volts or more are measured with the aid of a "volt box," which consists simply of a series of resistance coils having convenient relative values totaling say 100, 500, 1,000, 5,000, 10,000 ohms etc., from the left hand terminal. If the P.D. to be measured is in the neighbourhood of 100 volts it is connected across the 10,000 ohm resistance, FIG. 18.—COMPTON POTENTIOMETER

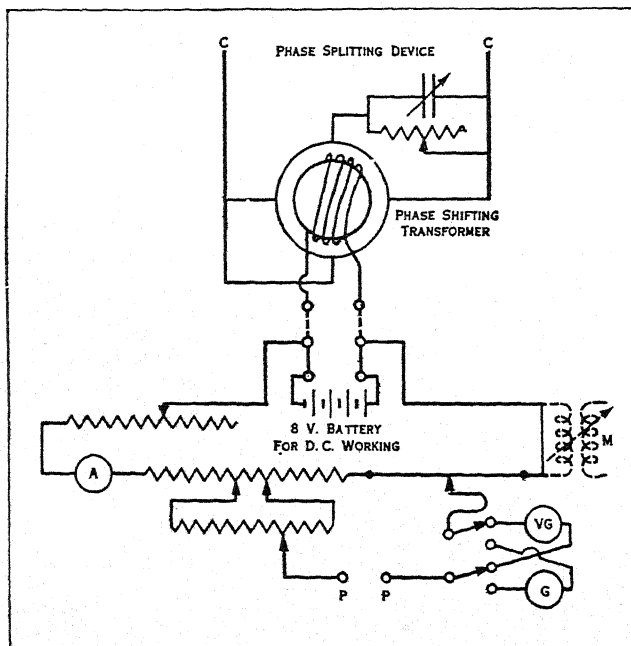

FIG. 18.—COMPTON POTENTIOMETER and the P.D. across the 100 ohm coil is balanced on the potentiometer. The actual P.D. is then read on the potentiometer multiplied by the ratio of the resistance 10,000/100 = 100, so that the instrument is equally direct reading. For the measurement of current it is passed through a standard resistance S of 1 ohm, 0.1 ohm, or 0.01 ohm, etc., and since the P.D. $V = Si$, $i = \frac{V}{S}$. For example, if

a current of the order of 100 amperes is to be measured, a resistance of 0.01 ohm is employed and if the P.D. across it measured by the potentiometer is 1.2635 volts, the current is 126.35 amperes.

The wide range of application and accuracy of the potentiometer has led to the devising of a number of different forms. In Germany and the United States, dial potentiometers based on the original form of Feussner are most generally used, the device being equivalent to two dial resistance boxes in series and mechanically coupled so that any increase of the resistance in one box is accompanied by an equal decrease in the resistance in the other,

FROM DRYSDALE, "JOURNAL OF SCIENTIFIC INSTRUMENTS"

FIG. 19.—DRYSDALE-TINSLEY A.C. OR D.C. POTENTIOMETER

and the total resistance and consequently the current remains constant. This is practically effected by making each dial with 20 coils and two contacts moved by the same handle. Special potentiometers for measuring very small P.D.'s such as thermo e.m.f.'s have been devised by Hausrath and Diesselhorst, in which no sliding contacts are encountered in the galvanometer circuit.

Alternating Current Potentiometers.—The great range, adaptability, and accuracy of the potentiometer for direct current measurements, led to a strong desire for a similar instrument for alternating current testing, especially as the range of most alter-

nating current instruments is small. A suggestion was made by Swinburne for balancing an alternating P.D. against a direct one derived from a potentiometer by means of a differential quadrant electrometer, but this was almost impracticable owing to the low sensitivity of such an instrument; and the first sensitive and practical A.C. potentiometer was devised by Drysdale in 1910 on the principle of balancing two alternating P.D.'s, both in magnitude and phase, and using a telephone or vibration galvanometer as the detector. The schematic diagram of this potentiometer is shown in fig. 19. It consists of an ordinary dial and slide wire potentiometer with a dynamometer millimeter in series with its main circuit, and provided with a change-over switch so that it can be fed either with direct current from an 8-volt battery, or with alternating current from a special "phase shifting" transformer. This consists of a ring shaped primary wound like a two-phase induction motor (*q.v.*) both circuits of which are connected across the A.C. mains—one directly and the other through a variable condenser and resistance box, by adjusting which a constant uniformly rotating magnetic field is secured. The secondary consists of a slotted cylinder with a simple diametrical winding, and as this is turned in the primary the induced e.m.f. remains constant for all positions, but its phase alters by the same angle as that of the rotation. The potentiometer is first supplied with direct current and balanced against a standard cell in the ordinary manner, and the dynamometer then adjusted to a fiducial mark, by means of its zero adjustment; after which it is changed over to the transformer and its rheostats adjusted until the dynamometer indicates the same current, when the alternating P.D. for any position of its potential contacts will be the same as that for direct current. The P.D. across any part of a circuit supplied from the same A.C. mains can then be balanced by moving the potentiometer contacts and turning the transformer, a vibration galvanometer being used which is comparable in sensitiveness to the ordinary moving coil galvanometer. When balance has been obtained, the magnitude of the P.D. is read off from the potentiometer in the ordinary way, and its phase angle or cosine or sine from a pointer and dial on the transformer. The P.D.'s and currents of any magnitude can be measured with the same volt-boxes and shunts, as for direct current, provided they are sufficiently non-inductive, and power by measuring the P.D. and current and applying the formula $W = Vi \cos \phi$. Inductances, capacities, and alternating magnetic fields can also equally easily be measured, if the frequency of the supply is known. For accurate measurements, the wave form of the supply must be fairly closely sinusoidal, and its frequency must be constant.

Three other alternating current potentiometers on a somewhat different principle have since been evolved. An alternating P.D. may be represented as a vector, as it has magnitude and direction (phase angle), and such a vector may be defined either by this magnitude and angle (polar coordinates) or by its two rectangular components (Cartesian coordinates). The Drysdale potentiometer may therefore be called a polar potentiometer, and is the only one of this class, but the Cartesian principle may be employed, and the potentiometers of Larsen, Campbell, Gall, and Pedersen are on that principle.

In the Larsen instrument (1910) an ordinary potentiometer is connected in series with the primary of a variable standard of mutual inductance M as in fig. 20. If i is the current through the potentiometer, it produces a P.D. $V_1 = Ri$ in phase with i across its contacts if R is the resistance between them, and also an e.m.f. $V_2 = M\omega$ across the secondary of the mutual inductance and in quadrature with i , where ω is the pulsance ($2\pi \times$ frequency) so that if the secondary is joined in series with one of the contacts of the potentiometer, any P.D. can be balanced by moving the contacts and turning the secondary of the mutual inductance standard (recently improved by W. A. Campbell).

In the Gall "Coordinate" potentiometer (1923), two potentiometers fed with two equal currents in quadrature supplied from a special transformer are employed; while the Pedersen instrument consists of two similar potentiometers in series with an inductance and a condenser respectively, the two circuits being connected in parallel across the supply.

VI. CAPACITY AND INDUCTANCE MEASURING INSTRUMENTS

Measurements of capacity and inductance are generally made by comparison with fixed or variable standard condensers or inductances. Condensers are of various forms, fixed condensers of high capacity from 0.001 to many microfarads, variable vane condensers of low capacity such as are used in radio work, standard air condensers, and high voltage glass condensers of the Leyden jar type.

High capacity fixed condensers are generally made of rectangular sheets of tinfoil between somewhat larger sheets of paper impregnated with paraffin wax. Each tinfoil sheet is provided with a projection or lug at one side, and alternate sheets have their lugs projecting in different places so that they can be connected together. Where a sufficient number of tinfoil and paper sheets have been laid together to give the required capacity the whole condenser is pressed between hot plates so as to form a solid block when cold, the alternate lugs are soldered together and connected to the terminals, and the whole block inserted in a wooden or metal case which is filled up solid with paraffin wax. For highly accurate standards thin sheets of the best ruby mica are substituted for the paper, and these sheets are frequently silvered on one side to form the plates, the silvering being removed for a short distance around the edges. A number of such paper or mica condensers are frequently included in a single case and can be used singly or in parallel, and dial condensers resembling resistance boxes, enabling the capacity to be adjusted from 0.001 to 1.111 microfarads are now commonly used.

Variable vane condensers consist of two sets of thin metal plates, usually of semicircular form, but of different diameters. The larger or fixed plates are built up on a frame so as to be accurately parallel to one another and equally spaced, while the smaller are threaded on a spindle with distance pieces between them so as also to be parallel and similarly spaced. The spindle is mounted in the frame so that the movable plates or vanes can turn between the fixed plates without touching them, and the two systems of fixed and moving plates are insulated from one another. An insulating handle provided with a pointer or a rotating dial enables the spindle to be turned, and the capacity varies continuously, from a low minimum value when the moving vanes are outside the fixed plates, to a maximum when they are completely inside them. By inserting the whole system in a case filled with oil both the capacity and maximum safe P.D. of the condenser may be considerably increased. The vanes are sometimes made of various forms in order to obtain a "square law" variation of capacity with angle, or a uniform frequency scale, etc.

Standard air condensers are only used for fundamental measurements and usually consist of a number of concentric accurately turned and measured cylinders on an insulating base so that their capacity can be calculated from the dimensions.

The most simple method of comparing the capacity of condensers is by the direct deflection method using a ballistic galvanometer (*q.v.*). If a condenser of capacity C is connected to a battery of e.m.f. E , it suddenly becomes charged with a quantity $Q = CE$, so that if two condensers of capacities C_1 and C_2 are connected successively to the same battery $Q_1 = C_1E$, and $Q_2 = C_2E$;

thus $\frac{Q_2}{Q_1} = \frac{C_2}{C_1} = \frac{D_2}{D_1}$, where D_1 and D_2 are the corresponding swings of the ballistic galvanometer.

Inductance standards may be either fixed or variable, and of self or mutual inductance. Fixed self-inductance standards are simply coils wound on rigid insulating bobbins, so as to have constant conformation. Marble is used for the most accurate, and carefully seasoned paraffined teak or boxwood for the ordinary standards. The first accurate variable inductance standard or variometer was that of Ayrton and Perry, and consisted of two coils each of about ten inches diameter wound in single layers on

circular wooden or ebonite formers curved so as to be parts of spheres and to enable one to fit as closely as possible inside the other. The inner coil was mounted on a spindle passing through the outer coil and having a pointer reading on a large dial at the top. The two coils were connected in series through flexible leads, and when they were parallel but the current passed round them in opposite directions their inductance was very low as the magnetic effects of the two coils almost neutralized each other, while on turning the inner coil round, the magnetic field (and therefore the inductance) increased steadily to a maximum when it was again parallel to the fixed coil. By careful construction a ten-fold range of inductance was secured.

FIG. 21.—HENLEY'S ELEC-TROSCOPE

In addition there are a number of fixed bobbins with primary and secondary windings which can be thrown into the circuit when this is desired.

Capacity and inductance measurements are now most commonly made by bridge methods using alternating current and telephones or vibration galvanometers, and such bridges allow of condensers, self, or mutual inductances to be compared in any combination. The best known forms of such bridges are those of de Sauty, Maxwell, Campbell, Drysdale and Schering.

VII. ELECTROSTATIC INSTRUMENTS

Electroscopes and Electrometers.—As their names indicate, these instruments are intended respectively for the detection and measurement of electric charges or differences of potential. Electroscopes were the first electrical instruments to be devised, and take their origin from William Gilbert (1544-1603), who first developed the knowledge of electrical phenomena from the isolated fact known to the ancient Greeks, that amber could be electrified by friction. His electroscope consisted simply of a light pivoted metallic needle, either end of which was attracted on the approach of an electrified body.

FIG. 22.—CAVALLO'S ELECTROSCOPE

The next step was to utilize the repulsion of two similarly electrified bodies. Benjamin Franklin, employing two linen threads hanging close together, and du Fay, Canton, Henley and Cavello double straw or pith ball electroscopes. Henley's electroscope (fig. 21) was a crude form of electrometer, and consisted of a pith ball suspended at the lower end of a light pivoted arm and normally just touching a metal sleeve. When the latter was charged, it imparted part of its charge to the pith ball and repelled it, and the amount of the charge was roughly indicated by an arc divided in degrees with its centre at the pivot. Cavallo's electroscope (*c.* 1770) was the prototype of the modern repulsion electroscopes, having a glass bell jar with a metal stem sealed into its neck (fig. 22). At the top of this stem was a bell-shaped metal cap A, which served as a charging knob and also protected the glass and insulation of the stem from rain if the instrument was used in the open air; while at the bottom of the

stem two pith balls were suspended by fine silver wires. Two metal strips, B and C, were cemented on the inner surface of the bell jar and connected to earth. In 1782 Volta increased the sensitiveness of this form of electroscope by adding a condenser, and Faraday showed that for its indications to have a definite meaning the interior of the glass vessel should as far as possible be covered with metal, leaving only small spaces for the observations of the movements of pith balls. In 1787 Abraham Bennet substituted gold leaves for the pith balls, the form of electroscope shown in fig. 23, in which the stem carrying the gold leaves and charging knob is supported on a rectangular glass frame inside the bell jar which is coated on the inside by a number of strips T of tin-foil, all connected to a terminal on the base, which can be connected to earth. The interior of the instrument is kept perfectly dry by means of a vessel containing calcium chloride and sulphuric acid, and an ebonite plug slides on the upper part of the stem. This plug normally closes the jar, but when the instrument is in use, it is slightly raised, leaving a small air space between the stem and the cap of the bell jar.

FIG. 23.—GOLD LEAF ELECTROSCOPE

Until about the commencement of the present century electroscopes were little used, except for teaching purposes in connection with electrostatics, but the discovery of radio-active materials and their power of discharging a charged body by ionization led M. and Mme. P. Curie to employ the rate of discharge of an electroscope as the best means of detecting the intensity of radio-active bodies, and a large number of new forms of electroscope have been introduced. That of M. and Mme. Curie is diagrammatically shown in fig. 24. It consists of a

FIG. 24.—CURIE'S ELECTROSCOPE

small brass case having a block of sulphur SS at its top, from which a metal strip B with a gold leaf L depends. The case is provided with two holes at its sides and a horizontal metal wire carries a charging knob C projecting through one of these holes and a condenser plate P' at its other end. A second condenser plate P, just below the first, is connected to the case. The instrument is first charged by the knob C until the gold leaf L diverges from the strip B by a convenient amount, after which a cap is fixed over C and the leaf should maintain its position for some time if the insulation is satisfactory. On inserting a small amount of radio-active material between the plates P and P', however, the ionization of the air between the plates causes the charge to leak away, and the rate of fall of the leaf L, which can be observed in a microscope through a window in the case, measures the amount of radio activity of the material.

Somewhat similar forms of electroscopes for radio-active measurements were made by Elster and Geitel, and by C. T. R. Wilson (1901), but in 1903 a great improvement was made by the latter in his tilted electroscope (fig. 25). In this instrument a single gold leaf L is employed which is attracted towards a plate P by connecting a battery of about 200 volts between the plate and the case of the instrument. Any charge of the gold leaf L then causes it to be attracted more or less strongly towards P, and it is found that if the whole case is tilted as shown, a position can be formed at which the instrument is extremely sensitive, and the tip of the gold leaf moves several millimetres when its potential is raised by one volt. The latest improvement in this type of instrument has been made by Wilson and Kaye (fig. 26), and is similar to the above except that the case is permanently tilted

FIG. 25.—WILSON'S ELECTROSCOPE

through about 45° and the final adjustment of sensitiveness is made by varying the distance of the plate P by turning the micrometer head D. With 200 volts on the plate this electroscope gives a deflection of three or four divisions on the scale in the observing microscope for only 0.01 volt on the leaf.

The electroscope employed for radio-activity investigations, as well as the early electroscope of Henley, are in reality crude forms of electrometers, as they are actually used for approximate measurements. But the term electrometer is generally restricted to instruments intended for accurate measurements of potential differences, and designed to have a more or less definite law. The first instruments of this kind were on the "attracted disc" principle, which seems to have originated in 1746 by Daniel Gralath of Danzig, and to have been termed by him an "electrometer"; but the earliest practical forms were those of A. Volta and Sir Wm. Snow-Harris, in which a flat horizontal disc was suspended from the arm of a balance just over

FIG. 26.—WILSON AND KAYE ELEC. TROSCOPE

FIG. 27.—SNOW-HARRIS'S DISK ELECTROMETER

so that the P.D. between the plates is the same as that between the coatings of the jar. Snow-Harris found that the weight required to restore balance was proportional to the square of the charge or the P.D. of the jar.

In 1857 Lord Kelvin turned his great mathematical and inventive skill to the subject of electrometers, and produced two

forms which have persisted with only detailed improvements to the present day. The first form was derived from the attracted disc electrometer, but had the very important addition of a "guard ring," which made its indications of absolute value. In the simple attracted disc electrometer the electrostatic field between the two plates is not uniform, as the lines of force curve round from the edges of the two discs. But if the fixed disc is made much larger than the suspended one, and the latter is surrounded by a plate which nearly touches it all round, then if the movable plate is exactly in the same plane as the surrounding plate when the measurement is made, the electrostatic field between the suspended and fixed plates will be practically uniform, and it can be proved theoretically that the force in dynes between them \pm will be given by the expression $f = \frac{A V^2}{8 \pi d^2}$, where

V is the P.D. between the plates in electrostatic units of 300 volts, A the area of the suspended plate in square centimetres,

FIG. 28.—KELVIN'S PORTABLE ELECTROMETER

and d the distance between the suspended and fixed plates in centimetres, so that $V = d \sqrt{\frac{8\pi g W}{A}}$. d and A are known, therefore, the P.D., V can be determined directly from the force required to balance the attraction.

Lord Kelvin employed this principle in two forms of electrometer, one of them being known as his portable electrometer, fig. 28, the essential parts of which are shown diagrammatically in fig. 29. H.H. is a plain disc of metal fixed inside the bottom of a glass jar, which is coated inside and outside with tinfoil to form a small Leyden jar. In the middle of this disc H.H. a square hole F is cut, and a slightly smaller square plate of aluminium foil provided with an arm at one side is mounted on a horizontal stretched wire so that it will just swing through the hole F like a trap door. The wire is given an initial twist so that the aluminium plate normally rests a little below the upper surface of the disc H.H., and the arm which is provided with a crutch and cross wire is therefore tilted upwards. A circular plate G is fixed on the end of a micrometer screw above the disc H and is connected through the metal cover to the outer coating of the jar. When there is a difference of potential between the two coatings of the jar, and therefore between the two plates, the aluminium plate is attracted upwards and by varying the distance between the plates by the micrometer screw it may be made to come into exact register with the plane of the disc H.H. when the indicating arm will be at zero. As the force required to attract the disc to this position is always the same, the P.D. required to obtain balance is simply proportional to the distance d between the plates which is indicated by the reading on the head of the micrometer screw. The absolute electrometer (fig. 30) is similar in principle but, the guard plate B and aluminium trap door H are near the top of the glass case and the attracting plate A is mounted just below them on the micrometer screw. The trap door is suspended on springs so as normally to be a little above the lower surface of the guard plate, and the force necessary to bring it into exact register can be initially found by placing weights on the disc and observing the position of the latter through the lens L. When this force is known, any P.D. can be measured by connecting it to the two plates and turning the micrometer screw till the aluminium plate is brought

FIG. 29

BY PERMISSION OF KELVIN, BOTTOMLEY AND BAIRD
FIG. 30.—KELVIN'S ABSOLUTE ELECTROMETER

to register, the formula being $V = d \sqrt{\frac{8\pi g W}{A}}$, where W is the weight initially required to produce register and g is the attraction of gravity.

The second type of electrometer was developed from the symmetrical electrometer initially devised by T. G. Behrens in 1806 and modified by J. G. von Bohnenberger. In this type a single gold leaf is suspended midway between two vertical metal plates between which a dry pile is connected. If then the leaf is charged it will move towards the plate of opposite polarity. Fechner and Hankel made further improvements; the latter substituting a battery for the dry pile, and adding adjustments to the plates and a

scale for measuring the movements of the leaf. Lord Kelvin greatly improved this type of instrument in his quadrant electrometer, the essential features of which are shown in fig. 31. A flat circular metal box is cut into four equal sections or quadrants A, B, C, D, and each section is supported on an insulating pillar and provided with a terminal, the opposite quadrant A and D and B and C being connected together by wires. A light flat paddle shaped aluminium vane U, shown by the dotted lines, is suspended by a bifilar cocoon silk suspension exactly in the centre of the quadrants and normally symmetrically between them as shown. From the centre of this needle hangs a fine platinum wire, which dips into sulphuric acid in the bottom of the glass containing vessel. This acid is conducting and it also serves the quadruple function of forming the inner coating of a Leyden jar, or keeping the interior of the apparatus dry, of establishing contact with the vane or needle, and of damping the movements of the latter. The outer surface of the glass container is partially coated with

FIG. 31

strips of tinfoil to form the outer coating of the jar. If this jar is charged, the needle can be maintained at a constant high potential by means of a small electrical machine or "replenisher" and a gauge, and if a small P.D. is then applied between the two pairs of quadrants the needle will turn so that a smaller portion of it is between the quadrants of similar potential and a larger portion between those of opposite potential to that of the needle, and its deflection can be observed by attaching a light concave mirror to the stem of the needle, and employing a lamp and scale as in reflecting galvanometers (*q.v.*). If V is the potential of the needle and V_1 and V_2 the potentials of the two pairs of quadrants respectively, theory indicates that the deflection $D = k(v_2 - v_1) \{V - \frac{1}{2}(v_1 + v_2)\}$ where k is a constant of the instrument. Unfortunately, Hopkinson, in 1885, and Ayrton Perry and Sumpner the following year, noticed that this law did not hold in the Kelvin electrometer, as instead of the deflection for a given P.D. across the quadrants rising proportionally with increase of potential of the needle, it increased up to a certain potential, after which there was little further increase, and in some cases a diminution. The latter investigators traced this action to openings in a guard tube which was employed

BY PERMISSION OF KELVIN, BOTTOMLEY AND BAIRD
FIG. 32.—KELVIN'S QUADRANT ELECTROMETER

to screen the platinum wire from external electrical disturbances, and devised an electrometer in which magnetic control was substituted for the bifilar silk suspension, and the quadrants were more exposed and more easily adjustable, thus enabling the theoretical law to be fulfilled, and with increase of sensitiveness. This improvement was of great importance, as it enabled the electrometer to be used as an accurate wattmeter (*q.v.*) for use in alternating current circuits, and this application was independently suggested in 1881 by Professors Ayrton and G. F. Fitzgerald and by M. A. Patier.

The invention of the quartz fibre by Prof. C. V. Boys has enabled quadrant electrometers to be made of much greater sensitiveness, owing to its extremely small and constant control. Among them that of Dr. F. Dolezalek (fig. 33) has been very successful, because of its high sensitiveness and low electrostatic capacity. The needle and quadrants are made of very small size; the latter being supported on short pillars of amber which give very high insulation, while the needle is of paper thinly coated with silver foil so as to have very small inertia and almost critical damping with the very small control of the quartz fibre. The latter

is rendered sufficiently conducting to charge the needle by dipping it in the first place into a solution of some hygroscopic salt, such as calcium chloride, so that its surface is always moist, or better by gilding it. The whole system is enclosed, like a galvanometer, in a brass case, which shields it from draughts and external electrostatic fields and the deflections are obtained by a small concave mirror on the needle, through a window in the case. A torsion

FIG. 33.—DOLEZALEK'S QUADRANT ELECTROMETER

head on the top of the suspension can be employed to adjust the zero of the instrument. With a quartz fibre suspension 60 mm. long and 0.009 mm. diameter and a potential of 110 volts on the needle, its periodic time was 18 sec. and a deflection of 130 mm. on a scale at 2 metres distance was obtained with a P.D. of 0.1 volt between the quadrants. Even greater sensitiveness has recently been secured with this type of instrument by the Cambridge Instrument Co. The latest improvement in the quadrant electrometer has been made by Prof. A. Compton, who has found that by slightly inclining the plane of the needle and giving a vertical adjustment to one of the quadrants, the control can be varied down to zero or even to a negative value. An instrument of this type with a gilded quartz suspension of 0.002 to 0.005 mm. diameter has given from 15 to 140 mm. deflection at a metre with 50 volts on the needle and only 0.01 volt between the quadrants, but the time to reach a steady deflection at the higher sensitivity is about 90 sec.

On the other hand the requirements of radio-activity research has caused the "string electrometer," based on the original instruments of Behrens and von Bonenberger, to be developed into instruments of high sensitivity, low capacity and rapid response by the aid of gilded quartz fibres. In a form of string electrometer made by the Cambridge Instrument company, a single quartz fibre of 0.002 or 0.003 mm. diameter suspended symmetrically between two plates with 25 volts between them, will give a deflection of .044 mm. or about 5.5 scale divisions on a microscope for 1 volt on the needle with a critically damped period of under 1 second. Prof. Lindemann has produced a deflectional "quadrant" electrometer having a 0.004 vertical gilded quartz fibre under slight tension, and two gilded glass fibres 2 cm. long and 0.02 mm. diameter cemented transversely and symmetrically upon it to serve as a needle. The ends of this needle move between four fixed plates serving as quadrants and the whole system is enclosed in a small sealed metal box with windows above and below, so that it can be placed on the stage of an ordinary microscope. Prof. Lindemann's deflectional "quadrant" electrometer is an instrument which gives .4 mm. deflection or 136 divisions on the

microscope for 0.35 volts between the quadrant plates and 1 volt on the needle.

Electrostatic Voltmeters.—For the measurement of high P.D.'s especially above a few hundred volts, electrostatic voltmeters are largely used as they have the great advantage of only requiring an infinitesimal current and power consumption and of being equally suitable for direct and alternating P.D.'s, in that they are entirely free from inductive errors. There are two main types of such voltmeters derived from Lord Kelvin's quadrant electrometer, and from Snow-Harris' attracted disc electrometer respectively (*q.v.*), but the latter are only used for very high P.D.'s of many thousands of volts.

When the electrometer principle was first applied to voltmeters, P.D.'s of only 100 or 200 volts were in use, and high sensitivity was consequently essential. The first practical electrostatic voltmeter was the "multicellular" form devised by Lord Kelvin in 1867 (fig. 34) and was equivalent to a number of quadrant electrometers arranged vertically above one another, their vanes or "needles" being mounted on a common stem so as to add their torques. Two sets of quadrant plates only were employed in each set, and were opposite one another and connected together to one pole of the circuit, the vanes being suspended by a fine wire and connected to the other pole. When the system was at zero, the vane system hung so that it was just about to enter between the fixed quadrants at two opposite edges. When a P.D. was applied between the vanes and quadrants the former were drawn further and further in against the torsion of the suspension as the P.D. was increased, and the P.D. could be indicated by a pointer attached to the vertical spindle on a scale as shown. This instrument was very similar to the variable vane condensers now so largely used for broadcasting sets and, in fact, its operation, like that of all electrometers, depends on this variable capacity. The energy stored in a condenser of capacity C and with a P.D. V between its plates is $E = \frac{1}{2} CV^2$, so that the

force between them $F = \frac{\partial E}{\partial x} = \frac{1}{2} V^2 \frac{\partial C}{\partial x}$, where x is the distance

between them; or the torque $T = \frac{\partial E}{\partial \theta} = \frac{1}{2} V^2 \frac{\partial C}{\partial \theta}$, where θ is the angle of rotation of the vanes. In the multicellular voltmeter, as

BY PERMISSION OF KELVIN, BOTTOMLEY AND BAIRD

FIG. 34.—KELVIN'S MULTICELLULAR ELECTROSTATIC VOLTMETER

in the vane condenser, the capacity is nearly proportional to the area over which the moving and fixed vanes overlap, *i.e.*, to the angle θ , so that $\frac{\partial C}{\partial \theta}$ is nearly constant. Thus, the torque, and

consequently the deflection θ , is approximately proportional to the square of the P.D. until the moving vanes are drawn nearly completely in, after which the increase of the deflection diminishes. Such voltmeters therefore only commence to have a useful reading at a moderately high fraction of their maximum voltage, but then have a widening scale, closing up again as the maximum is approached. This is a very suitable scale for supply circuits, though less suitable for general measurement.

The multicellular voltmeter came into fairly considerable use

FROM GLAZEBROOK, "DICTIONARY OF APPLIED PHYSICS" (MACMILLAN)

FIG. 35.—ELECTROSTATIC VOLTMETER ("QUARTER CYLINDER" PRINCIPLE)

for circuits up to a few hundred volts, but was very slow in indication owing to the large inertia of its vane system. It was damped by a disc at the bottom of the spindle which turned in a vessel of oil.

For higher voltages Lord Kelvin introduced another form having only two fixed vanes in a vertical plane, with a single vane moving system having a pivoted horizontal axis. Ayrton and Mather devised electrostatic voltmeters for both low and high P.D.'s on what they termed the "quarter cylinder" principle. It may perhaps best be described as a quadrant electrometer in which the moving vanes are bent over so as to form portions of cylinders parallel to the axis, and the quadrants are then also portions of cylinders which are arranged concentrically. This construction has the advantage of reducing the moment of inertia and increasing the rigidity of the system for a given capacity, and therefore of increasing the rapidity of reading. Suspended instruments of this type have been made for P.D.'s down to 80 volts and pivoted horizontal axis switchboard instruments for 3,000 volts or more. These latter instruments are damped by piston air dampers, but Carpentier has adopted the same form, but mounted between the poles of a powerful horseshoe permanent magnet which produces the damping by the eddy currents induced in the moving system. Extra high voltage voltmeters have been made by the Westinghouse company and others on the same lines, but with the system immersed in oil which gives a greater dielectric strength against arcing, a greater torque owing to the increase of capacity, and damping by the viscosity of the oil. Compressed nitrogen has also been employed in electrostatic voltmeters for reducing liability to spark, and the formation of ozone. For very high voltages up to hundreds of thousands of volts, the instruments would become very cumbersome owing to the large distances required to avoid flashing over, but the range of the above instruments may be almost indefinitely extended for A.C. measurement by connecting a condenser in series with the voltmeter as originally proposed by Ayrton and Perry. If the capacity of this condenser is equal to that of the voltmeter, twice the P.D. will be required for the same deflection, or if it is one-ninth of the voltmeter capacity the required P.D. will be multiplied tenfold, and so on, so that an instrument normally reading to 5,000 volts can have its range extended to 50,000 volts or more. This is generally effected by connecting one terminal of the voltmeter to a plate or sphere on an insulating pillar with another plate at an adjustable distance near to it. On the other hand the Snow-Harris attracted disc electrometer (*q.v.*) has been adapted as a high voltage voltmeter by Lord Kelvin in his Volt balance, and by Jona, Siemens and Halske, Grau and others.

INSUBRES, a Celtic people of upper Italy, the most powerful in Gallia Transpadana. Livy states that Bellovesus and his Gauls, having crossed the Alps and defeated the Etruscans near the Ticinus, found themselves in the territory of the Insubres (also the name of a *pagus* of the Aedui). Here they built a city and called it Mediolanum (Milan), after the name of a village in their home in Gallia Transalpina. The name Insubres thus appears applied to the inhabitants (1) of the Aeduan *pagus*, (2) of the territory in Gallia Transpadana occupied by Bellovesus, (3) to the founders of Mediolanum. From 222 to 195 B.C. the Insubres were frequently at war with the Romans. In 222 B.C. they were defeated at Clastidium by M. Claudius Marcellus, who gained the *spolia opima* by slaying with his own hand their king Viridomarus, and in 194 B.C. they were finally subdued by L. Valerius Flaccus.

See H. Nissen, *Italische Landeskunde*, ii. 179 (1902); A. Holder, *Alteltischer Sprachschatz*, ii. (1904).

INSULATOR, in electricity, is a non-conducting device, or material, used to separate two electrical conductors.

INSULIN. Insulin belongs to the group of substances known as hormones and is secreted into the blood by cells which are situated in or near the pancreas. In the mammalia, in which the pancreas is well defined, the insulin secreting cells lie in scattered groups, called the isles of Langerhans, distributed among the relatively much larger groups, or acini, of pancreatic cells. In certain fishes in which the pancreas does not occur as a definite gland, but is spread out diffusely in the mesentery, *e.g.*, in Lophius and Myoxocephalus, the islet cells form compact encapsulated glands called the principal islets which are often of considerable size and contain no pancreatic (acinar) cells.

Evidence that insulin is present in the pancreas of mammals was originally furnished in 1889 by Mehring and Minkowski. They found that complete extirpation of the gland in dogs immediately caused severe diabetes, and it was not long before the hypothesis was formulated that this must be due to the withdrawal from the body of a hormone having the function of regulating the metabolism of the carbohydrates. The name insulin was suggested (by Sir E. Sharpey Schafer) for this hormone in the belief that it comes from the islets, and many attempts were made to extract it from the pancreas, but with little success. In 1921, however, Banting and Best, working under the direction of J. J. R. Macleod, found that extracts of partially degenerated pancreas contained the hormone. This method was based on the supposition that the powerful digestive ferments of the intact pancreas destroy the insulin during the process of extraction and on the knowledge that the cells which secrete these ferments undergo degeneration more rapidly than those of the islets after the pancreatic ducts have been tied (Schultz and Ssobolew). This observation demonstrated that insulin does exist in the pancreas, and the next step was to devise a method for extracting it in more purified form and in quantity from normal pancreas. Alcohol was found to be a suitable extractive, in that it dissolved the insulin and at the same time inhibited the action of the digestive ferments, and Collip succeeded, in 1922, in sufficiently purifying the alcoholic extracts, by a process of fractional precipitation, so that

they could be injected subcutaneously in man without causing local irritation. Very potent extracts were also prepared from the principal islets of fishes. Further purification of the extracts was effected by precipitating the insulin, either by adjustment of the reaction (isoelectric precipitation) or by means of picric acid followed by treatment with alcoholic hydrochloric acid (insulin hydrochloride). Extracts capable of lowering the blood sugar have also been prepared from other organs than the pancreas, or principal islets, but it is doubtful if their action is really due to insulin. Certain guanidin salts also depress the blood sugar.

The function of insulin is to control those chemical processes of the body which are concerned in the preparation of the food-stuffs for oxidation in the tissues. The material which is immediately oxidized to produce this energy is carbohydrate, a supply of which is always present, as glycogen, in the muscles where it is formed out of the sugar of the blood. This sugar comes from the liver and is derived either from sugar absorbed from the intestine and temporarily stored in this organ as glycogen, or when digestion is not going on, from glycogen which has been manufactured out of protein and fats (gluconeogenesis). Insulin controls the rate of supply of sugar from the liver in proportion to the utilization of glycogen by the muscles.

When insulin is absent from the blood, as after pancreatectomy or when the islets are destroyed by disease (diabetes), sugar production occurs in the liver more rapidly than glycogen formation so that glycogen disappears from this organ, the blood sugar becomes very high (hyperglycaemia) and sugar appears in the urine (glycosuria). At a later stage substances known as the ketone bodies also appear in the blood and urine (ketonuria), being derived from the incomplete oxidation, chiefly of fatty acid but partly also of certain of the amino acids. Death ultimately occurs, either because of starvation caused by the excessive using up of the available foodstuffs of the body, or because of toxic effects for which the ketone bodies are believed to be largely responsible (diabetic coma). Insulin promptly removes all of these symptoms when injected subcutaneously or intravenously, but is inactive when given by mouth, because it is destroyed by the digestive ferments (pepsin) of the stomach. The effect passes off in a few hours, so that the injections must be repeated twice daily. When this is done the symptoms of diabetes remain absent apparently indefinitely, at least two dogs that were depancreatized for over four years were still living in Dec. 1927 and in excellent condition as a result of insulin treatment. In diabetes in man, although the islets are more or less diseased they are never completely destroyed, so that when treatment with insulin is continued for some time the damaged islets may possibly become regenerated.

One of the most significant effects of insulin when given to diabetic animals is that it immediately causes glycogen to be again deposited in the liver and a change occurs in the respiratory metabolism. In a normal animal fed on carbohydrates the ratio between the oxygen absorbed and the carbon dioxide expired, the so-called respiratory quotient, is near to unity, whereas in complete diabetes it never rises above 0.7. When insulin is given the diabetic, the quotient behaves as in the normal animal. Insulin therefore has three fundamental effects in diabetes, it restrains the excessive gluconeogenesis, it stimulates glycogen formation and it raises the respiratory quotient. When insulin is injected into normal animals the blood sugar, which usually stands at about 0.105%, rapidly diminishes and when it reaches a level at between 0.040 and 0.050% curious symptoms supervene. In most laboratory animals these hypoglycaemic symptoms consist at first of nervous hyperexcitability leading to convulsions, and later of coma and fall of temperature. That the symptoms are related to the disappearance of free glucose from the blood is indicated by the fact that they are promptly removed by restoring glucose to the blood, either by giving sugar by mouth or by injecting solutions of glucose subcutaneously or intravenously. Glucose is conspicuously more efficient as an antidote than any other sugar, even than mannose and laevulose which are so closely related to it chemically. The substitution of one hydrogen atom in the glucose molecule by some other radicle such as a methyl (CH_3) group, robs it entirely of its antidoting powers. The mechanism by which

excess of insulin causes hypoglycaemia in the normal animal is not clearly understood.

Since insulin can now be prepared in crystalline form (J. J. Abel and Geyling) and a readily dried, solid, compound can be formed with hydrochloric acid—insulin hydrochloride—it may be weighed out for medicinal use, but it is more convenient to use it in liquid form which keeps well in acid reaction. The strength in actual insulin of the liquid is determined by a biological method which depends on the lowering of blood sugar in a normal rabbit. The strength is gauged in units, one unit of insulin being originally defined as that amount which on subcutaneous injection will lower the percentage of blood sugar to the convulsive level, 0.045%, for a period of 5 hours in a fasting rabbit of 2 kg. weight. This original unit was subsequently reduced to one-third. The assay is now carried out by a comparative method in which the hypoglycaemic effect of the solution to be tested is compared with that of a solution containing an accurately weighed amount of insulin hydrochloride. In order to ensure uniformity in the strength of insulin manufactured in different countries the Health Committee of the League of Nations has set aside a sufficient quantity of dried insulin hydrochloride of which 1 mg. contains 8 units. Testing laboratories maintain their own standards, but they can have them checked against the international standard from time to time. By such international uniformity in strength of insulin the diabetic patient is insured against variable dosage and the risk of hypoglycaemic symptoms. (J. J. R. MacL.)

INSURANCE, ARTICLES ON. The following deal with insurance in its various branches: ACCIDENT INSURANCE, PERSONAL; AGRICULTURAL INSURANCE; CREDIT, INSOLVENCY OR BAD DEBT INSURANCE; ENGINEERING INSURANCE; FIRE INSURANCE; INDUSTRIAL INSURANCE; INSURANCE: *An Introduction*; INSURANCE, MISCELLANEOUS: *Burglary, Drivers' Policies, Fidelity, Guarantee, Plate Glass, Property Owners' Indemnity, Third Party, etc.*; INSURANCE, POST OFFICE FACILITIES; LIFE INSURANCE; MARINE INSURANCE; MOTOR VEHICLES INSURANCE; SOLDIERS' INSURANCE; UNEMPLOYMENT INSURANCE.

Separate articles appear under the headings NATIONAL INSURANCE, HEALTH; NATIONAL INSURANCE, WIDOWS' AND ORPHANS'.

A cognate matter of great importance is the subject of pensions, which will be found under the following headings: INVALIDITY PENSIONS; OLD AGE PENSIONS; PENSIONS, CIVIL SERVICE AND MUNICIPAL; PENSIONS, NAVY, ARMY AND AIR FORCE; PENSIONS, PERPETUAL; PENSIONS, POLITICAL; PENSIONS, IN THE UNITED STATES; SUPERANNUATION; WAR PENSIONS.

A special article on ANNUITY is very important as bearing not only upon insurance schemes, but upon house purchase, hire purchase, etc. Finally, EXPECTATION OF LIFE; GUARANTEE; LIFE TABLES; RE-INSURANCE; TITLE GUARANTEE COMPANIES and WORKMEN'S COMPENSATION are the subjects of special articles under those headings.

INSURANCE, INTRODUCTION TO. Insurance is the practical device by which civilized man protects himself against the contingencies of life. He has for centuries realized the regularity with which the law of average operates when great numbers are involved and has employed his knowledge to provide by insurance against the hazards to which the products of his enterprise and his industry are at all times subject. The principle of insurance was admirably stated by a select committee of the House of Commons who, in reporting (in 1825) on the laws relating to friendly societies, said: "Whenever there is a contingency, the cheapest way of providing against it is by uniting with others, so that each man may subject himself to a small deprivation, in order that no man may be subjected to a great loss. He, upon whom the contingency does not fall, does not get

his money back again, nor does he get for it any visible or tangible benefit; but he obtains security against ruin and consequent peace of mind. He, upon whom the contingency does fall, gets all that those, whom fortune has exempted from it, have lost in hard money, and is thus enabled to sustain an event which would otherwise overwhelm him." It does not detract from the general truth of this pronouncement that a certain part of the premiums paid for insurance is absorbed in the expenses necessarily attendant on the conduct of the business, nor is it a demerit of the system that insurance, since it produces nothing, adds nothing to the wealth of the world. It may, indeed, be claimed to its credit, in this connection, that in practice, with the assessment and modification of premiums with reference to the risks incurred, the system tends, by encouraging the adoption of preventive measures of various kinds, to diminish that waste and loss the fear of which has called it into existence. Due weight being given to the benefits of insurance, both direct and indirect, it must be concluded that its cost to the community, as represented by the maintenance of the great number of persons whose energies it absorbs, and by the profits of those who risk their capital in providing it, is far outweighed by the value of the service which it renders. This, indeed, is as true of insurance on human life, at any rate in its more substantial forms, as it is of insurance against the risk of loss of material things; e.g., by fire or marine disaster.

So far as concerns the trading profits of insurance, which constitute a comparatively minor element in its cost, Great Britain is specially favoured in that the pioneering enterprise of the British insurance companies, and the high reputation which they have long enjoyed, have attracted to them a substantial share in the world's insurance business. The profits on this business cannot readily be computed, but are generally accepted as making a useful contribution to the "invisible surplus" by which the balance of international trade is maintained.

The special position of marine insurance in regard to the commercial prosperity of Great Britain is vividly indicated by Sir Norman Hill in his contribution to *War and Insurance*, one of the series of works on the economic and social history of the World War published on behalf of the Carnegie Endowment for International Peace. Here he sets out shortly the mechanism of the method by which the nation is, in great measure, fed and clothed by supplies from overseas. "By far the greater proportion of the cargoes at any time afloat belong not to the producers, the merchants, or the consumers but to the financial interests who have discounted bills of exchange representing the purchase price of the goods, and who hold as their security the bills of lading and policies of marine insurance. . . . The security against all trading risks is ample because the advance is repaid out of the selling price of the goods on the completion of the voyage, or if the goods be lost, out of the insurance money. Moreover the bills of exchange against which the advances are made afford the most convenient means for the adjustment of international exchange and they therefore pass freely from hand to hand and from country to country in the process of these adjustments. In fact, international finance is in very great measure based on the security afforded by the bill of exchange drawn against goods in transit, and it is to that extent dependent on the security of not only the bill of lading for the goods, but also on adequate insurance against the risks incident to the transit." On a closely related point it may be said that marine insurance has supplied the model for a system of foreign credit insurance which has recently been established at the instance of the Overseas Trade department to stimulate the export trade of the United Kingdom.

Insurance or Assurance.—The terms insurance and assurance are employed somewhat indiscriminately to indicate "the action of insuring or securing the value of property in the event of its being lost, or of securing the payment of a specified sum in the event of a person's death." This quotation is from the *Oxford English dictionary*. Babbage proposed, so long ago as 1826, that the word assurance should be reserved for contracts relating to life, on the ground, in effect, that in this case the event on which the policy depends is a certainty, and that insurance would more appropriately be applied to contracts relating to con-

tingencies. While this convenient distinction has found much favour, it has been challenged in other quarters and is not universally adopted. In the United States the term "insurance" is generally used.

Historical References.—Marine risks were the subject of the earliest form of insurances. Setting aside the attractive but debatable proposition that insurance was recognizable as an element in the maritime commerce of antiquity, there is ample evidence of its use in the middle ages. A "Chamber of Insurance" established in London under a patent granted by Queen Elizabeth in 1574, the object of which was to register all contracts of insurance negotiated and to record their terms for reference in case of dispute, was a comparatively late-comer, similar bodies having been founded in Barcelona (probably in the 13th century) and in Bruges (1510). The first English statute on "assurance" appeared in 1601 and dealt with marine risks. The earliest known life policy, which followed strictly the form of marine insurance, was effected in 1583.

Scope of Insurance.—Insurance was limited, until recent times, to life, marine and fire risks. Modern developments have added other subjects; e.g., the risk of personal accident, sickness, employers' liability, burglary, motoring, aviation and loss of livestock. Insurance under some of these headings includes the wide range of risks involving liability to civil action in respect of loss of life or damage to property.

While commercial insurance of every class expands continuously, in correspondence with the growth of population and with the enlargement of human necessities and desires, the developments of life insurance recently are of special interest. So far as Great Britain is concerned the growth of the business under "ordinary" policies, providing substantial sums for premiums payable annually, half-yearly or quarterly, has somewhat more than kept pace with the increase of population and the change in the value of money. In North America this class of insurance has advanced remarkably, while in various European States the business has exhibited considerable recuperative power in face of the difficulties created by the depreciation or collapse of currencies. Industrial life assurance has made great progress on both sides of the Atlantic; the number of policies of this type in force in Great Britain and Ireland at the end of 1926 was about 72 millions, an average of nearly two policies for every member of the industrial population. The number of such policies in the United States at the end of 1926 is also reported to have been 72 millions, while nearly four million policies were in force in Canada. Industrial assurance is also practised widely in Australia. The latest development of life insurance for industrial workers originated in the United States under the title of "Group insurance," and has lately reached the British Isles. It is stated that some six millions of American work-people are interested in insurances under this plan, by which the employer effects a year-to-year insurance on the life of each person in his employment through the medium of a single policy covering his whole staff. In certain cases the benefits of the plan have been extended, with the aid of contributions from the assenting employees, to cover sickness and accident and to provide pensions on retirement. There is, perhaps, less scope for such extensions in Great Britain, where the ground is largely covered by friendly societies, by State insurance, and, in growing measure, by superannuation or pension funds connected with particular establishments.

Interesting developments in other directions exemplify the methods by which British insurance is adapted to the requirements of the ordinary citizen. For example, the occupier who owns his dwelling, a rapidly increasing class in present conditions, is able through his building society, or other medium by which his purchase has been financed, to couple with his mortgage a policy of a special type whereby the remaining burden of his debt is lifted from the shoulders of his family in the event of his death before his instalments have been completed. Worthy of mention also is the type of policy—under various names—by which the householder may, by a single contract, insure his personal belongings against such diverse misadventures as fire, gas or boiler explo-

sion, burglary, etc., and may cover his risks as an employer in respect of his domestic staff. Generally, it may be said that while the business of the majority of insurance companies is conducted on fairly conventional lines there is practically no type of contingency for which insurance protection cannot be obtained from adventurous underwriters at Lloyd's or elsewhere.

State Insurance.—Insurance has taken a prominent place in the modern conceptions of the functions of the State. The compulsory protection of the worker against the contingencies by which his livelihood was most obviously beset originated in Germany where in the years 1884-86 compulsory schemes of insurance against sickness and accident (including medical treatment) for substantially the whole of the wage-earning community were brought into operation. These were supplemented later by schemes relating to invalidity and old age. That these measures took deep root and met the requirements of the people is sufficiently indicated by the fact that they survived the shock of the loss of reserves on the collapse of the mark in 1923. Austria followed the German empire in the adoption of compulsory State insurance and in 1911 it was introduced into Great Britain and Ireland by the National Insurance Act. Although a modest and experimental scheme of unemployment insurance was incorporated in this act, its principal subjects were sickness and disablement (including, with these, the provision of medical treatment and medicine), and over 15 million workers, of whom nearly one-third were women, were brought within its scope. An enlarged scheme of unemployment insurance, applying to about 11 million wage-earners was introduced in 1920, and in 1925 provision was made for pensions and allowances to widows and orphans and for pensions to the insured and their wives on the attainment of the age of 65. A corresponding Act was passed in the same year by the Parliament of Northern Ireland. The scope of this latest scheme is slightly wider than that of the health insurance measure, and while the number of persons who are insured under the scheme in the United Kingdom approaches 17 millions, the number of persons who are interested as actual or potential beneficiaries is about 31½ millions.

Taking the whole of the schemes together, and bearing in mind the provision made by the Workmen's Compensation Act, which is also, in general, safeguarded by insurance (in this case at the cost of the employer alone), it may be said that the industrial workers of Great Britain and Northern Ireland are more fully protected by the action of the State in respect of the more serious contingencies of life than those of any other country. Developments, however, still proceed elsewhere. The General Conference of the International Labour Organization of the League of Nations (10th Session, 1927) has proposed that the member States should be invited to subscribe to conventions relating to sickness insurance for workers in (1) industry and commerce and domestic service and (2) agriculture, and it is understood that the consideration of other risks is to follow. Save, therefore, in North America, where differences of economic conditions are responsible, at present, for differences of outlook, compulsory State insurance, in relation to a comprehensive range of subjects, seems likely to spread to the whole of the civilized world.

Where State insurance invades a field of effort such as that of the British friendly societies, a measure of controversy is, of course, inevitable. Certain distinctive merits must, however, be conceded to compulsory national schemes, even by those who are most reluctant to concur in the new activities of the State. Looking at the matter as it concerns this country it cannot be denied, on the one hand, that the thousands of registered friendly societies made, and continue to make, a substantial provision against sickness and other contingencies in the case of perhaps four millions of those who come within the national scheme; it has also to be recognized that apart from these bodies, whose operations are on a permanent and fairly stable basis, sickness insurance, though on a lower grade of quality, was very widely practised through unregistered bodies. But, on the other hand, there remained several millions of wage-earners, women especially, whom existing agencies had failed to reach, or at any rate to attract. National insurance, enforced by public authority, succeeded at the point

where voluntary agencies had failed, and brought under a measure of protection, moreover, all who from advancing years or inferior health were ineligible for membership of a friendly society. Again, by the scheme for pensions at 65 the State was able to enforce protective measures in regard to which private effort, though exercised untiringly over many years, had failed—and that conspicuously—to persuade.

Unemployment insurance as a possible subject of State action presented similar features. Available to many of those engaged in the highly skilled and well organized trades, it made little more than an exceptional appearance in the constitution of the newer trades unions which cater largely for the unskilled classes, while to the millions of unorganized workers it was wholly unattainable. When it is added that where it was practised its finance rested generally on the basis of a single craft, with all the extremes of risk that this implies, it will be realized that the time was ripe for comprehensive action such as the State could certainly take and no other agency had offered to initiate.

Widows' Pensions.—But it is, perhaps, in respect of widows' pensions that compulsion has been of chief value. "Adverse selection" is an element against which insurance on a voluntary basis has constantly to contend, and where the subject is such as pensions to widows and temporary allowances to dependent children this element would operate on a voluntary scheme, dependent on its own resources, with quite paralysing effect. Few with the exception of the married would insure; few, if any, of the insured would keep their policies up when, with the lapse of years, the need of them seemed to disappear. In the result the cost of insurance would be altogether prohibitive. The State, by compulsion applied from early youth to the whole of the wage-earning population, could obviously secure (with or without a subsidy) what private effort dared not attempt. The need for such a scheme, no less than its usefulness in practice, is attested by the fact that in the earliest months of the scheme it relieved the boards of guardians in England and Wales of expenditure at the rate of nearly £2,000,000 a year. This indeed is the lesser relief; the greater is the removal from the ranks of pauperism of scores, if not hundreds, of thousands of fatherless children.

Personnel and Statistics.—The professional interests of the insurance official and the technical education of the junior grades are served by many organizations of which three British bodies may be singled out, both on the ground of seniority and as enjoying the dignity of incorporation under Royal Charter. These are the Institute of Actuaries, the Faculty of Actuaries in Scotland and the Chartered Insurance Institute. The number of those engaged, in all grades, in the practice of insurance at the last census of Great Britain is given as 133,000, of whom one-third were women. Those employees whose remuneration is not more than £250 a year are insurable under the Unemployment Insurance Acts, and in 1927 this class included 86,000 persons.

The statutory returns of the British insurance companies and societies (which do not include the underwriters at Lloyd's) show that in the latest year of account (generally 1926) for which figures are available the total amount received in premiums for business of all kinds was £242,000,000. Of this total £134,000,000 were attributable to insurance contracts other than life, and it is probable that a very substantial part represented business overseas. Claims reached a total of £137,000,000, and reserves of all kinds, of which the funds accumulated under life assurance contracts represented about four-fifths, exceeded the massive aggregate of £1,000,000,000. (A. W. W.)

INSURANCE: MISCELLANEOUS. Under this head are considered various types of insurance which are not dealt with under separate heads (*see* INSURANCE ARTICLES).

Burglary: Private Dwellings.—Policies are issued to cover the risks of house-breaking and larceny, although larceny is excluded if plural tenancy exists or, in the case of a flat, if it is not self contained. Premiums are based on the full value of the total contents, an excess premium being charged if valuables, *i.e.*, gold and silver articles, jewellery and furs, exceed one-third of the whole. Damage to the building caused by burglars, for which the insured is responsible, is included in the normal policy.

Business Premises.—The cover is more restricted, the larceny risk always being excluded, whilst frequently only theft following "actual violent and forcible entry to the premises" is insured. The rates vary with the nature of the stock to be insured and the means of protection employed. Insurances are generally effected for the full value of the stock at risk and the condition of average (similar to that used in fire business) is freely used.

Cash Insurances.—Cash may be insured whilst in transit in the custody of an employee of the insured (including the integrity risk) and thereafter whilst contained in an approved safe or strongroom until paid away. The premium is calculated on the estimated carryings, subject to adjustment at the end of the period of insurance. The limit of liability for any one occurrence is the maximum amount stated by the insured to be carried at any one time. Cash is also insured whilst deposited in an approved securely locked safe, but loss following the use of the key, unless obtained by threat or violence, is excluded.

"All Risks" Insurances.—Such cover is frequently sought in respect of jewellery, furs, works of art and other items of value, and insurances may include or exclude the fire risk. The cover is usually comprehensive and excludes only losses due to deterioration, vermin, war and kindred risks. The sum set against each item in the policy is generally agreed to be its value as between insurer and insured when the policy is effected and represents the insurers' liability in the event of total loss.

Fidelity Guarantee.—Commercial guarantees are sought for most responsible officials handling money and are provided by insurers after satisfactory enquiries have been made as regards the antecedents of the applicant. The employer's statement to the insurers forms the basis of the contract and discloses the system of check used, which must not be altered without the consent of the insurers. Policies are issued either for individuals or a collective guarantee may be given for an entire staff. In the latter event each employee is mentioned by name and the sum guaranteed on his behalf is stated.

Plate Glass Insurance.—Essentially an insurance against breakage, the risk of fire is excluded from the plate glass policy. Only glass specified in the policy is insured, and wooden framework and lettering, the latter, unless specially insured, is not covered. Premiums are calculated according to the superficial area and type of the glass to be insured. Stained and other valuable glass, lettering and painting are rated on a percentage of value.

Third-party Insurance.—Indemnities in respect of the legal liability of individuals or corporations to pay compensation to third parties for personal injuries or damage to their property caused by negligence on the part of an employer or his employees, or due to defects in the ways, works, machinery or plant used in the employer's business, are almost universally sought. Policies are issued to cover the insured's entire legal liability, excluding, however, liability to a member of his family or to a person in his service, or liability assumed under contract. Within the limits of indemnity selected the insured is relieved of all monetary responsibility, including law costs incurred in defending claims, fraudulent or otherwise. All claims negotiations are conducted by the insurers who may if they wish relieve themselves of all further liability at any time by paying to the insured the maximum sum for which they are liable in respect of any one accident. The limit of indemnity for any one accident mentioned in the policy is defined as meaning "any one accident or series of accidents arising out of one event." Policies suitably modified are issued to almost every trade and may be obtained to cover most contingencies likely to affect third parties.

Property Owners' Indemnity.—Such policies cover the liability of the insured to pay compensation for personal injuries to and damage to the property of third parties caused by defects in buildings. Claims are commonly due to falling slates, tiles and copings, whilst poorer class properties are subject to falling ceilings, defective railings and staircases and many other causes. Such insurances are similar in operation and conditions to third-party policies, and may be extended to include liability which may be incurred in connection with defective stop-cocks and defective sanitary arrangements.

(A. G. M. B.)

Hail Insurance.—Hail Insurance is carried mostly to protect growing crops, policies being written for the principal ones. The coverage is limited to a given maximum amount per acre for each type of crop, and the rates vary with the crop and the territory. In general the liability of the Insurance Company applies only after the crop is in a healthy growing condition.

Earthquake Insurance.—Policies for earthquake insurance protect from all direct loss or damage from earthquake or volcanic eruptions and removal from premises endangered by them. A 10% exemption clause and a 70% coinsurance clause are customary. The policies do not assume liability for fire, wind or tidal waves or loss due to neglect of the insured to diligently protect his property.

Tourist Baggage Insurance.—Personal effects can be insured while in transit within defined geographical limits. Usually the protection covers fire, lightning, cyclone, flood, navigation and transportation risks and theft provided the insured promptly notify the local police authorities. Some policies omit theft or limit the liability to a stipulated per cent of the amount of the policy on furs, musical instruments, jewelry, plate, clothes and watches. The amount of premium is dependent on the size of the policy and the length of time it has to run.

Explosion Insurance.—These policies are designed to cover loss or damage from all explosions except those originating within steam boilers, pipes, flywheels, engines and machinery, as these are covered by Engineering Insurance policies (*q.v.*).

Use and Occupancy Insurance.—Use and occupancy insurance is also known as business interruption indemnity insurance. It is needed particularly by manufacturers of advertised and popular goods, merchants, hotels, laundries, theatres, warehouse and public utilities. The policies protect against losses resulting from interruption or suspension of business that follow a fire or some other calamity. Partial payments are provided for partial interruption of business and it is considered advisable for full protection to be insured for an amount equal to one year's estimated net profit and fixed expenses. Shorter terms are available and are often used on similar policies to protect from loss of rent resulting from the same causes.

INSURANCE: POST OFFICE FACILITIES. The grant of Government life insurances in Great Britain through the agency of the Post Office was inaugurated by the Government Annuities Act, 1864. The avowed object of the scheme was to provide facilities for members of the working classes to insure their lives for moderate sums with the advantages of Government security.

The Act empowered the National Debt Commissioners to make ordinary life insurance contracts with any person between the ages of 16 and 60, but not for a greater sum than £100 or for less than £20, and authorized the Postmaster General to direct his officers to receive premiums and pay claims on behalf of the National Debt Commissioners. The rates of premium were to be calculated on the basis of 3% interest, and in such a manner as to form a fund adequate to meet all claims without entailing any charge, whether for claims or expenses, on the Consolidated Fund.

From the outset the amount of business transacted under the scheme was much smaller than had been anticipated, and in 1882 a Select Committee of the House of Commons was appointed to enquire into its operation. An amended scheme on the lines of the committee's recommendations was prepared, and received statutory sanction in the Government Annuities Act, 1882. Revised rates of premium were introduced and new forms of policies were made available, but the most important alteration was the linking up of the insurance system with the Post Office Savings Bank.

The scheme still failed to achieve the success that had been hoped for, and in 1892 it became the subject of an investigation by a departmental committee. The principal result was the adop-

tion of reduced rates of premiums. The new tables were introduced in 1896, and together with the regulations governing the conduct of the business, which were made at the same time, remain in force to-day (1928). The revised scheme was no more successful than its predecessors, and another departmental committee was set up in 1907. Their report, published in 1908, contained a number of recommendations for increasing the usefulness and popularity of the system, but no action was taken until Jan. 1914, when the stamp premium system was instituted.

Under this scheme the premiums are payable by means of ordinary postage stamps to be affixed weekly by the insured person in a premium book. At the end of each 13 weeks the stamped page containing the premiums for the quarter is withdrawn on presentation of the book at a post office. The scheme is available for persons of either sex between the ages of 14 and 50.

The tables show the amounts which are insured at death by the payment until age 60 of premiums varying from 2d. to 1s. per week, and therefore invite comparison with those of industrial insurance companies which show the sums assured by weekly premiums of one penny or multiples thereof payable throughout life. Owing to the shorter period over which premiums are payable, the sums assured under the Post Office scheme, particularly for the smallest premiums which are the most heavily loaded for expenses, are generally less than those quoted by the companies, and it is not improbable that many prospective insureds obtain the impression that the terms offered by the Post Office are less generous than they are in reality.
